Thanks Paul,

What do you mean by a thin wire? #20 magnet wire, #26?

Sounds like I can make my own and very easily, with just a 18mm length of
(not sure what size) wire.

Hi John,

Thanks for the info. Much more specific. I didn't realize I could make one from #18. I have the latest ARRL handbook, but maybe wasn't looking in the right place to see that info.

I don't have an inductance meter, so I am not sure how I would tune it. It is for 433.92MHz.

http://www.radiotronix.com/downloads/433_pair.pdf

The document is at the above address.

Thank you again,
Joe

Thanks Reg,

I will download that program. It sounded kind of small to me too. I don't
use smd because I don't know how.

The link to the schematic is:
http://www.radiotronix.com/downloads/433_pair.pdf

That's a hollow 'motherhood' statement - no one could disagree with that because your statement doesn't actually say anything (except to partially define the word 'patent').

Back to The Question:

As you well know, a patent doesn't necessarily mean that anything functional has actually been built. This is self-evident by the numerous US patents for the impossible (or for the presently impossible). I was NOT asking about patents, I asked (quite clearly I might add) if anyone had actually built the subject item at the subject scale before the subject CNN news item.

It is a very simple question.

CNN story (they were first) true or false?

> ...the assignee of the patent is what's important.

That assumes that there is any money to be made from it within the term. I believe that something like 99.99+% of all patents are money losing propositions. They're apparently a worse investment on average than lottery tickets.

> ...wouldn't hurt to give the man some well-deserved credit.

Of course.

The CNN story claimed that those people were first. All the RRAA 'harbour seals' starting barking that it was old news - most of them just didn't read the story carefully. Now W1XYZ drops by with his patent portfolio but didn't answer the very simple question - who actually made one first (which is where this long thread started).

It is a very simple question.

Not patents.

Who made one first?

CNN guys or W1XYZ or anyone else?

So far - no one has provided anything to prove the CNN story was incorrect.

Thanks for playing.

"Energy sources" !
What is the total length of pipe lines involved with oil in the MidEast?
Using 24/7 time lines does America have enough troops or reservists to
position every 100 yards
to prevent tampering ? The largest user of oil has the economy that goes
down the fastest while
the supplier only needs enough for cooking. If 'push comes to shove' what
would be the result
of that scenario ? Listen to the debate tonight and hear what the
candidates have to say about that.
General Electric is ahead of the game by buying up the majoratory of
railroad cars in the U.S.for
shipping goods by rail like Europe in the event of oil problems Just look
at any highway to measure
the trucking industry dependance on fuel and then estimate the time and
expense needed to replace
the highways with rail tracks. Maybe we should learn to live with people
with religeons different
from our own and force a return of the holy places that have been stolen
from them.
Bush authorised more building on the West Bank stating it will be difficult
to remove them once
they have built their homes. This said regardless of the thoughts of the
rest of the World who we hope to
ask to come and help us and kill all those who have the temererity to resist
the land take over.
Do we in the U.S. have to wait for hindsight to determine whether it is
possible to turn a corner when
all are in a free fall mode without the provision of allies to hold a safety
net?

Hi, Joe -

You won't tune it with an inductance meter. You could try constructing one of those RF millivoltmeters in the ARRL manual and reading the voltage across a (leadless) 50 Ohm output resistor. Then try kinking your wire (inductor) to see if you can tune it that way.

I strongly recommend you get a copy of "The ARRL UHF/Microwave Experimenter's Manual" and read it like there is no tomorrow. It will open your eyes about things that happen to wires at 434 MHz. For example, if you've made a few calculations, you may have discovered that an 18 nH inductor has a reactance of almost 50 Ohms at 434 MHz. That's why you are told to have no leads on components at that frequency. Have you seen a 440 MHz power amplifier? You will notice the absence of many inductors and capacitors compared to lower frequency amplifiers. That's because they use a few inches of PCB material to make inductors, capacitors, transmission lines.

If they did make leaded 18 nH inductors, how long would the leads be? If you purchase an 18 nH SMD inductor and put two 1/4 inch long #22 AWG wires on it, you will then have a 27 nH inductor. That doesn't solve your problem.

Your problem at 434 MHz will be that every component (with leads) that you add, you will also add several nH of inductance if your leads are longer than .1 inches or so.

If you analyze the receiving network, you will see that, if the antenna is 50 Ohms, the receiver sees 50 Ohms. So the network appears to simply be a filter. I would loose the receiver PI network, for sure. I think the transmitter is similar.

If it were me, I would forget both PI networks and even forget the pad on the transmitter. Put a cotton pickin' 6.8 inch antenna on the module and try it. Arrange your module so the antenna can be attached directly to the pin of the module, if possible.

Or, do these transmitters require the PI network to stay within FCC limits?

Anyway, good luck.

John

Thru hole inductors were traditionally calibrated so that the inductance met
spec with 1/2 inch total length including leads, and not over a ground
plane. The smallest value of thru hole inductor I have ever seen is
27 nH. The true inductance (without the leads) of this inductor is
probably around 18 nH or less. Also, the inductance of thru hole
inductors typically drops about 5% over a ground plane.

You're probably better off winding your own air core inductor
and tweak it until your circuit is tuned where you want it.

Hi John,

In the old days, this question use to appear on the FCC's serious
tests - also required math too.

You already demonstrated as much with:

I don't understand what you're driving at here, Richard. I'm saying that an analysis of the PI network shows that it serves no "matching" purpose if the antenna is 50 Ohms and the receiver wants to see 50 Ohms. Its only purpose seems to be to provide a narrow bandwidth. Does the receiver need it? Probably not, unless there are a other transmitters in near by operating on an adjacent frequency.

As for the transmitter, perhaps it needs a filter, perhaps not. But, is a PI sufficient to meet any regulations if it does require a filter? Does the transmitter not meet the regulations without it? I remember hearing that these transmitters use SAW devices. Aren't SAW devices filters? All I'm saying is that, if you can meet the FCC rules without the PI filter, you don't need the filter at all.

73,
John

Hi John

SAW, surface acoustic wave, filters are not transmitter pass filters.

As for the need, that is simple: OF COURSE it needs filtering. Simply observing the manufacturer's requirements reveals that:
>In most cases, the output of the transmitter may need a low-pass LC filter to reduce harmonic emissions.
As for matching:
>The output of the oscillator is derived directly from the collector of the oscillator transistor. It is, therefore, very sensitive to VSWR.
This, alone, demands filtering to reduce harmonics.

As for SAW filters. It has one, and uses it in the conventional manner (not as an output filter) for frequency determination in the oscillator.

Tongue-in-cheek, Jack,

There's no need to tell ME what the British are like.

After 79 years I know!

It's just that YOU are better at it than we EVER were.

But, 8 years too late, WE are now taking care of puppy-dog Tony.

Just make sure YOU do likewise with George.

And we will BOTH get on fine with each other.

Only three more to sort out - Teheran, Pyongyang and finally Beijing.

Your Coalition and Tea Party Colleague -
---
Reg.

Reg Edwards, G4FGQ wrote:
"For "Weapons of Mass Destruction" read "Multi-nationals", "Wall Street", Energy Resources", "CIA", "Pentagon" and "N.American Branch of the Mafia". Bush and Blair just obey instructions."

Old adage: "He who pays the piper, calls the tune." In democracies, politicians spend fortunes from donors to get elected. The donors make sure they are credited with their campaign contributions, which they say are only given to the politicians so that the donor`s side of critical issues gets a fair hearing in the legislature, or from the administration, or whatever.

I guess Reg`s point is that his list of items contains some of the real causes of the war in Iraq, not "Weapons of Mass Destruction", the reason given at the time of the invasion. I think Bush and Blair really believed they would find stockpiles of WMD in Iraq. Otherwise, why would Saddam not cooperate eagerly with the U.N. weapons inspectors? A reasonable person with a gun poked in his ear complies with the demands of his assailant. Only Jack Benny, an American frugal comedian when urged to decide if it were going to be his money or his life, responded with: "I`m thinking, I`m thinking!

For Saddam, being jailed and dispossessed of all those lovely palaces is surely worse than the presence of foreign inspectors is, a challenge to his sovereignty, which he lost too. He could also lose his life. He had to think nobody would come after him.

Just shows what happens when you have crazy people on both sides of a confrontation.

Best regards, Richard Harrison, KB5WZI

Since the inductor is only a two "pin" component and assume you have
two PCB tracks at a suitable distance from each other, soldering
should not be a problem even without SMD experience. Using a toothpick
or some other device to keep the component steady, first solder one
end, let it cool for awhile and then solder the other end.

By the way, what type of capacitor are you using for that 8 pF ? If it
is a leaded component, it might have quite a few nH of wire
inductance. In addition to the SMD inductor, I would also recommend a
SMD capacitor, since these have a lower self inductance. Soldering it
close to the inductor should not be any harder.

I suggest that you buy some cheap SMD resistors or capacitors with the
same size package as the inductor or capacitor you are going to use
and solder these to a Vero 0.1" strip board to get some confidence in
SMD soldering, before installing the real components into the module.

It also helps if you mount the gadget on a broom-stick and hold it at arm's length well above your head.

But you then need an extension lead for an earphone. You also have to shout loud.

news:<7_17d.3698$DV3.3543@bignews5.bellsouth.net>...
> What effect would explain the " better for DX"?
> Less Noise - Increased signal - Both?

The angles used for low band dx are very low in general. Below 10
degrees.
So naturally, you want an antenna that favors the lower angles, rather
than a cloudwarmer that favors many of them. Or even worse, straight
up. At night on 40m, my 10 ft mobile antenna is stronger 1000 miles
away, than my dipole here at the house which is about 40 ft up. The
mobile whip is much less efficient, but what power it does radiate, is
at the perfect angle for the path I'm working.
As far as the original poster, I'd use either the HF2V as a ground
plane, with elevated radials, or I'd extend the mast and run inv L's.
But I'm almost positive that the GP would smoke the inv L on 40m. Even
with as few as 4 radials. I've run the same antenna on 40m, and it
worked great. But on 80m, he would need double the radials, to equal
the same efficiency on 40m, not counting loading losses. Also, just
guessing , but I bet the lack of success with it the last two winters
was due to a lack of radials...You need a lot if ground mounted. Well,
unless you like a mediocre signal...:/ If he had 10 radials, elevated
at 32 or so ft, on 80m with that HF2V, I think it would work quite
well. They can slope down to the ground, but don't let them touch.
Probably better than anything else mentioned, being as the current is
elevated up off the ground. As far as radials, you should always think
in terms of wavelength off the ground. For the same height, the needed
number increases the lower in freq you go, for a certain efficiency.
On 40m, at 32 ft , it's a 1/4 wave up. At that height, 4 radials
equals about 60 on the ground.
But on 80m, it will only be an 1/8 wave up. So 4 radials would only
equal about 32 on the ground. And some will differ, but I find 32
radials on the ground to be fairly mediocre. And my ground is pretty
good as far as ground goes. Once you get to the equal of about 60
radials on the ground, it will really start to play. Or that's what I
notice. Yes, in theory, the difference should be small, but in the
real world it seems a quite noticable increase to me. MK

There are enough reasonable people in Iran and China that they can
come along on their own if enough are smart and all are lucky.
I've had students from both countries and they were quite bright and
rational.
Pyongyang is problematic and our own fault. Should have finished it in '53.

The patent is the only thing that matters in such new technology.

That's what makes Bob a 'player'.

He's a real person with a real patent. And, by golly, he has a real e-mail!

BTW, here's today's trivia question.

Carbon 14 dating is a mainstay for setting ages of things a few thousands of
years old.

Who--invented--it?

a) Isaac Asimov
b) Harold Urey
c) Linus Pauling
d) Louis Leakey

Not a trick question.

Any 'players'?

73,
Chip N1IR

For anyone interested in what an 18 nano-H inductor looks like under a magnifying glass -

3 turns of 0.33 mm diameter wire, wound on a 2.2 mm diameter former, over a length of 2.0 mm.

Its self-resonant frequency is 4.6 GHz and it is tuned to 1 GHz with a capacitor of 1.3 pF. Q = 330 at 1 GHz.

Joe, you're up against physics. 18nH is what you get moving a current
through just a couple of cm of straight wire. Before SMD, a microwave board
looked rather "fuzzy", with little tweaks of wire and snips of stripline. If
you want that 18 nH from one hole in a PCB to another one 01." away, then
you will have to bend that wire into a half loop. That ads inductance, so
the wire will have to be shortened some more.

SMD allows you to slap a lumped value into an exact location, without having
leads to worry about. The down side is that SMD is difficult to work with.
As usual, you have three choices: small, easy and workable. Pick any two.

I agree with H. McArthur should have had support from an A-bomb on Pyongyang, followed by similar strikes in China and Russia. We had a nuclear monopoly at that time. The Cold War would have been nipped in the bud.

We would have had to be extremely vigilant to find and destroy any nuclear threat, and keep the U.S. monopoly.

We just could not accept killing so many innocent people to control a hostile world. Good deeds are always punished?

Then all Nations are correct in pursueing the development of
nuclear weapons for defense since it is to be shown that even peace
loving nations would consider its use to protect its own interests.
All oil producing countries are aware that the U.S. contemplated
the occupation of some Mid East countries during the last oil crises
and have large stockpiles of weapons in Israel for that event. And is the
reason that
the U.S. has supplied bunker busting smart bombs to Israel which is
certainly
overkill for dirt trenches. These displayed intentions by those with nuclear
capability
demand pre emptive strikes by even the smallest nations to halt perceived
intentions.
If an A Bomb had been dropped on the Chinese in Korea would we now be
without fear
of retaliation at China's choosing? If Syria had a A bomb would America have
told Israel
to wipe out their nuclear power station? When America tells Israel to drop
the bunker
buster bombs on Iran can we be sure that Pakistan or other countries will
not come to the defense of Islam.
We in the U.S. have to start thinking of consequences before we follow movie
teachings that we can
take on the World at any time and at any place and for any reason. We are
not strong enough
to do that without allies if we are to preserve some land for the populace
to live on.

I believe at the time it would have been called the "MacArthur
method." Had Truman listened to him, P5 would have an IOTA number and
the world would be a better place.

And if Barry had been elected in '64, the world would be an even
better place.

Hi Reg, I suppose I understand what you meant, although I do not agree that the United States is or was imperialistic the way England was, and we were never as vile to each other, even in our own short Civil War. The most land we ask for from our conqured or liberated is enough to bury our dead on. That is certainly not Britain's history. And I am absolutely sure that neither you nor any Brit has any idea how you could be so absolutely vile to each other in your own country, Christian against Christian (yeh right!). Only the Africans behave as badly to each other as the Irish Protestants and Catholics do.

Just so you know, conservatives have already sent President Bush a strong message, and he is aware that a large majority of his supporters expect *major* changes in his policies, *after* he is re-elected. In my opinion, nothing that Kerry said sounded convincing with regard to the nuclear proliferation problem. Of course the United States is strong enough to fight and win two major wars on separate continents at the same time. We could fight and win three in fact. Just don't expect the kind of compassion in avoiding civilian casualties or surgical strikes that target structural rather than human assets in that event. No sane people in the world want to see things come to that, especially the Chinese. There are however several insane people in the world, namely the leader of North Korea, and the entire

nation of islam. "Friends" like France would still be useful enough, if for just one time, they could protect their *own* land in a world war, and not require more help at that from the US and Great Britain.

;-) Jack

We can "win" many more wars than just three at the same time
by landing on a flight deck and declaring 'mission accomplished.'
Why haven't the troops come home if we have 'won' the war.?
Or is it that from now on frontal engagements will not be fought anymore and
where we build a defensive position down town and only venture out in
daylight when CNN passes by.

Reg,
A 1/2 turn loop of the proper dimensions might be more practical. I recall
using one that was about .5 in high between .5 centers, made of #14 wire.
(it carried 10 amps). Don't remember the exact value, but it was probably a
little more than what he is looking for.

At any rate, as you say, it is important to add the inductance of the
circuit board traces to the inductor value. BTW, the last job I was on used
402 SM inductors down to about 10 nH, but that was at 2+ GHz.

Tam

## 40. Ground connections to a tower

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-01 20:24:24 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <Y1j7d.22205$kq6.11630366@news4.srv.hcvlny.cv.net>
Source record: 88834

I have a TX455 tower that I am beginning to ground and I could use some collective experience of the group. This is a 55-foot tower in a location not especially prone to lightning. I am trying to be reasonable without going overboard on grounding.

1. Where might I obtain the 1-inch nuts for the standard UST concrete stubs? And stainless steel washers to match? My local Home-Depot type places seem to stop at the 3/4-inch sizes.

2. There is no clearcut way to connect ground straps/wires to the tower. I have ground posts about 30 inches from each of the three concrete bolts holding the tower base. It seems reasonable to run a strap from a ground post to the 1-inch concrete bolts holding the tower base bracket. There is enough thread exposed above these to hold two (thin) SS washers and another 1-inch nut. This appears to be a convenient way to make the connection. I assume the SS washers would be needed to fight corrosion from the copper wire/strap to the zinc-dipped tower base.

3. I want radials for the tower (for a quarter-wave sloper). Would it be reasonable to connect multiple radials to each of three ground posts and then depend on the single wire/strap from the ground posts the three bolts holding the tower base? This is for 160/80/40/30 meter operation.

Thanks,

Bill
W2WO

**** Post for FREE via your newsreader at post.usenet.com ****

"Fractenna"
> The patent is the only thing that matters
> in such new technology.

<Yawn...> Oh sorry...

Look - anyone could 'patent' going into space in a cheap, reusable rocket like 'this' and like 'that'. What makes the evening news is when someone actually DOES it. Same thing for 'light antennas' - who did it first (couldn't care less who happened to apply for a patent if they didn't actually DO it).

When they changed the definition of 'reduction to practice' from 'send a working model' to 'just write it down', the whole patent system became a lawyers' game and a work of fiction in many cases.

> BTW, here's today's trivia question.
> Carbon 14 dating is a mainstay for setting ages
> of things a few thousands of years old.
> Who--invented--it?

Perhaps someone patented it in 1920.

The decay of Carbon-14 and it's relationship to cosmic rays, the atmosphere, life and death is a natural phenomenon. It wasn't really 'invented' (except by God and/or Nature), it was discovered (or developed) by W.F. Libby.

According to Encyclopedia Britannica 2003 Deluxe CD edition (oh so cool for $10):
"The carbon-14 method was developed by the American physicist Willard F. Libby about 1946."
"...he and his students developed the carbon-14 dating technique."
"[He] wrote Radiocarbon Dating (1952)."
"For this development he was honoured with the Nobel Prize for Chemistry in 1960."

From the WWW:
"In 1960, Libby was awarded the Nobel Prize in Chemistry for leading the team (namely, post-doc James Arnold and graduate student Ernie Anderson, with a $5,000 grant) that developed Carbon-14 dating."

"Martin Kamen discovered [Carbon-14] in 1940 in collaboration with the late Sam Ruben, a University of California, Berkeley chemist, while the two were working at the 60-inch cyclotron at the Lawrence Radiation Laboratory."

Do you know something the rest of the world doesn't?

Hi John,

That's what I have been doing. Just using a piece of 20 ga wire for an antenna, it is about 15cm in length (a vertical antenna). On the transmitter, I was using a loop, a piece of 20 ga wire with a 1 pf cap between the hot end of the antenna and the transmitter pin, other end grounded.

Last nite after I read all the responses, I went to the Handbook and looked at page 10.10. There is a graph at the bottom of the page that shows inductances of a straight piece of wire at that frequency. Anyway, I rigged up a 0.9" piece of 20ga wire between two 8pf ( I did not have 8.2pf) caps and the reception increased dramatically. My test method was: Receiver in my

house on a bench. TX outside about 80 feet away. In the old configuration, the receiver would sometimes receive the TX pulses. Once I put the TX inside my tool shed (about) the same distance away, the receiver would not pick up the signal. So after I rigged up my "almost" 18nH inductor and the 2 8pf caps, I repeated the experiment and the receiver was able to reliably receive the transmissions in both places. So I definitely saw an improvement.

As far as FCC goes, this frequency is supposed to be for ISM, and you can use it unlicensed subject to part 15, that's why my first attempt was to work on the receiver, not the TX, but I may experiment on the TX now also.

Thanks Reg,

I could not run the program solnoid3 on my computer for some reason. I am
using winblows xp.

I did improve the performance of my receiver tho. I checked the graph on
page 10.10 of the handbook and rigged up a straight piece of 20 ga wire for
my inductor. I don't know what the inductance actually is, but it improved
the performance greatly, which is all I was trying to do.

Best Regards,

Joe

Too bad the grounding wasn't thought about sooner so that 1-3 ground rods could have been put into the bottom of the hole dug for the base...

Try a Semi truck repair facility. Lugs on most large trucks range from
1" to 33mm. Washers should be available too, though Stainless might be
a stretch.

One reason the receiver improved may be because the filter was cutting out
all the wide band noise (other signals).

I can not recommend Ground Strap to ground the tower. Strapping makes
an excellent wick for rain water and will soon corrode. It is much
better to use a heavy copper wire. If you must use ground strap, be
sure to paint a heavy rubberized coating on all surfaces of the ground
strap.

>
> Eric N7DLV

Very good Eric. The other problem with "strap" (and we assume Bill Ogden meant braid) is that braid is is a poor DC ground, and not even close to the best choice for RF ground or bonding connector for lightning protection. Braid is only specified for grounding of vibrating machinery and other flexible requirements. Avoid any kind of braid for radio or bonding uses if possible, especially if it is not tinned.

SS washers between copper and galvanized tower will not isolate the connection at all. Acid rain will wash the copper oxides all over the tower studs as if it were connected directly.

Obtaining the best tower and coax shield grounding possible is important not only for lightning protection, but for protection from static charges which all towers and antennas are susceptable to. The RF grounds and radials etc must be an integral part of any lightning protection scheme. The only reminder is to avoid allowing a downconductor from rooftop air terminals, masts or tower from bonding to an RF radial component *until* the downconductor first connects to a deep ground rod.

Jack

Chip wrote:
"Who invented it (radiocarbon dating)?"

I`d rather date a real live girl.

All living things contain radiocarbon (carbon 14). It`s a radioactive isotope which appears in small concentration in the atmosphere from cosmic ray bombardment. After death, former living things no longer absorb the isotope. The radioactive isotope in the dead thing starts to decay at an exact and uniform rate. Its radiation half-life is 5,730 years.

Remnant radiation makes it possible to date things formerly living within the past 50,000 years. approximately.

The radiocarbon dating technique was developed by Dr. Willard F. Libby (1908-1980) in the late 1940s.

This comes from "The Handy Science Answer Book" of the Carnegie Library of Pittsburg.

Best regards, Richard Harrison, KB5WZI.

I buit an S shaped folded dipole like this for my camper years ago. Like you
I did nt want it for watching a lot of TV.Just get weather reports and such,
Mine was about 10 ft long before bending it into an S and I used a good
quality preamp with it. Actually I was quite surprised at how well it
worked.

Thanks to all the replies! Yes, I didn't probably have as many
radials down as I should for the HF2V. I think I will keep it stored
away and take my chances on an inverted v antenna and feed it with
ladder line. I am going to put a mast above the tower.

Just installed a Hustler mobile antenna on my van and while tuning it, it got so hot that the coil started to melt ( the cover) . What would cause this? Antenna was mounted on a trailer hitch mount, 42" fold-over mast, and with the 40 meter coil installed. At the time, the SWR was less than 1.5 to 1, and running less than 100 watts. Is it normal for these coils to run hot, even when matched?. The 20 meter coil started to get hot too. If this is normal, how much power am I loosing in the coil. Antenna seems to work well, everything else seems ok. Any Thoughts?

Hi Pete,

A poor, resistive connection (resistance in general).

>Antenna was mounted on a trailer hitch mount, 42" fold-over
>mast, and with the 40 meter coil installed.

Which would lead to a radiation resistance (for a one fortieth
wavelength antenna) of 2 Ohms.

>At the time, the SWR was
>less than 1.5 to 1,

Which could be explained (by other than tuning) to have been achieved
by inserting a resistance of 30 or 40 Ohms.

> and running less than 100 watts. Is it normal for
>these coils to run hot,

Even 50W into 30 or 40 Ohms gets things toasty.

>even when matched?.

A dummy load matches just as effectively and warmly.

>The 20 meter coil

Which would lead to a radiation resistance (for a one twentieth
wavelength antenna) of 8 Ohms.

>started to
>get hot too.

And probably a lower SWR too.

> If this is normal, how much power am I loosing in the coil.

Ah! The $64000 question. Probably all of it. The better question is
where is all the resistance coming from that makes this heat?

>Antenna seems to work well, everything else seems ok. Any Thoughts?
>Pete N1AGV

Antennas working pretty well and getting hot simultaneously should give pause to re-examining the concept of "working pretty well" (by what criteria, SWR?).

Follow the heat (literally). Wait for things to cool down and then key-down for a shorter period and try to narrow in on that part that warms first. Try one of those fish tank thermometers that is a sticky press on type using liquid crystal phase shifting displays (AKA mood ring technology). The heat is where the resistance is (and wire does not often qualify except at a poor connection point).

Any chance this is an old or defective antenna, with corrosion in the
winding?
Power dissipated in resistance rather than radiated, is what's making it get
hot.

Hi Ralph,

Yes, that could be it. I have not looked at it on my scope. I will probly do that tonite. Thanks for the idea. I know that before, the receiver was noisy as hell. I don't know if they are all like that, but I'll find out. What I was seeing was just a lot of what looked like random noise, till the TX was activated, then all the noise seemed to go away and just the code (about 680hz square waves) from the TX was visible. I am using the holtek ht12d on the receiver and holtek 12E on the transmitter.

Hi Richard,

Yes, an answer for the itinerant questioner.

But now for something completely different but wholly within the purview of light (let's see if they can get this one):

In an infinite universe filled with stars, every line of sight should eventually meet the surface of a star. The dimming of starlight with distance should be exactly canceled out by the increase in the number of stars you see as you look farther out, so the night sky should appear as bright as the surface of the sun - but it is not.

This paradox, was solved by:
Erle Stanley Gardner
Edgar Allen Poe
Edwin Powell Hubble
Edward Roscoe Murrow

Name the one who coined the paradox for extra credit.

That would be Hubble that solved the paradox, and the initial paradox was by Heinrich Olbers, although Jean-Phillippe Loys de Cheseaux (jeez Louise, whatta name!) dabbled in that too. Even Kepler to some extent - though he took the easy way out and decided the Universe must not be infinite.

I have not seen that question before, but will speculate that Edwin Hubble deserves the credit as he used "red shift" in the light from other galaxies to show that they are speeding away from us and our galaxy. In fact, they are accelerating so that the farther the galaxy is away from us, the faster it is moving away.

From continuous acceleration, the distant galaxy will eventually reach the speed of light. Then, light from the distsnt galaxy won`t reach us because it will tag along with the fast moving galaxy.

There may be a time shortage too as Einstein has shown time slows as a thing moves faster.

Hubble has also shown that the Doppler effect would shift the frequency lower as velocity of the retreating thing increases. Shift the frequency low enough and the wave is no longer described as light but may be classified as a millimeter radio wave.

Best regards, Richard Harrison, KB5WZI

A close and suggestive answer.

Hi All,

Well, it is notable that no "astronomer" got this one right ;-)

I will 'fess up in that it was a trick question because it contained a ringer (one that three out of three sprung for).

However two out of three got the extra credit question (Olber's Paradox). No doubt second tier, and to date silent, observers may chime in with "authority." ;-)

No, Hubble may have described an answer that satisfies the paradox, however the FIRST (1848) and ACCURATE response to this issue was written by Edgar Allen Poe in "Eureka!" what he calls a prose poem dedicated to Alexander von Humboldt:
"Were the succession of stars endless, then the background of the sky would present us an uniform luminosity, like that displayed by the Galaxy -- since there could be absolutely no point, in all that background, at which would not exist a star."

Poe's work is a very large monograph on the nature of electricity, gravitation and a very sophisticated description of the cosmology of cluster galaxies (including what are still current theories of condensation during stellar and planetary formation). To bring the paradox to a conclusion he offers: for our being able to view this totality of solar flux as a continuous sheet of luminosity requires that the universe must have existed FOREVER. The concept of light traversing space at less than instantaneous velocity (and that there are huge and vast distances involved) shows a deep consideration of the topic. This monograph is exceedingly developed with a style of irony that I enjoy.

This intelligence touches on a topic that I have broached on one other occasion. Poe was at one time an engineering student at West Point, THE pre-eminent engineering school of America (7 presidents were

engineers). Most of us only encounter his work through recitations of "The Raven," or, for many of us, with the drive-in movies produced by Roger Corman in the early 60s with Vincent Price et al ("The Tell-Tale Heart," "The Fall of the House of Usher," "The Pit and the Pendulum" and others).

To be accererating, there would have to be a force .

Where would this force be coming from and what pray tell is directing
it?

The speed of light is a constant in all reference frames. If a light
source were to be moving at the speed of light away from an observer,
an impossiblity in itself, the light would still be moving at c towards
the observer.

A very handy device for tracking this down would be an infrared thermometer. Radio Shack sells one for between 30 and 50 dollars, depending on whether it's on sale. It covers 0F to 400F, switchable to C or F, and when held close to an object will measure the temperature of a dime sized area or less.

I have never used mine for this purpose, but I have used it to check the temperature of transistor pairs in RF amplifiers as well as heat sinks in PCs. They are also handy to see if auto engine parts have cooled enough to work on.

Hi Richard,

Poe got it right. The greater portion of the night sky is as black now as it was in Poe's time - nothing has changed to render Poe's assessment incorrect.

" My general proposition, then, is this: -- In the Original Unity of the First Thing lies the Secondary Cause of All Things, with the Germ of their Inevitable Annihilation.

Poe is describing both concepts we now proclaim as the Big Bang, AND the Big Crunch.

"In speaking of what is ordinarily implied by the expression, 'Universe,' I shall take a phrase of limitation -- 'the Universe of stars.' Why this distinction is considered necessary, will be seen in the sequel.

"But even of treatises on the really limited, although always assumed as the un limited, Universe of stars, I know none in which a survey, even of this limited Universe, is so taken as to warrant deductions from its individuality."
...
" It seems to me that, in aiming at this latter effect, and, through it, at the consequences -- the conclusions -- the suggestions -- the speculations -- or, if nothing better offer itself, the mere guesses which may result from it -- we require something like a mental gyration on the heel. We need so rapid a revolution of all things about the central point of sight that, while the minutiae vanish altogether, even the more conspicuous objects become blended into one. Among the vanishing minutiae, in a survey of this kind, would be all exclusively terrestrial matters. The Earth would be considered in its planetary relations alone. A man, in this view, becomes mankind; mankind a member of the cosmical family of Intelligences."

These paragraphs introduce a literary device used by Poe to discuss the topic, a message found in a floating bottle - from the future:

" And now, before proceeding to our subject proper, let me beg the reader's attention to an extract or two from a somewhat remarkable

letter, which appears to have been found corked in a bottle and floating on the Mare Tenebrarum - an ocean well described by the Nubian geographer, Ptolemy Hephestion, but little frequented in modern days unless by the Transcendentalists and some other divers for crotchets. The date of this letter, I confess, surprises me even more particularly than its contents; for it seems to have been written in the year Two thousand eight hundred and forty-eight. As for the passages I am about to transcribe, they, I fancy, will speak for themselves."

I will pause here in anticipation of further inquiry. ;-)

Jim Pennino wrote:
"There has never been a contradictory observation that the speed of light is other than a constant, ever."

A.A. Michelson and E.W.Morley in 1881 measured the speed of light in the direction of the Earth and the speed of light at right angles to the Earth`s motion. No difference was found.

Light does have different speeds in different media. This causes light to bend when passing from one medium to another. The "speed of light" is through space or a vacuum. The more a substance bends light, the higher its refractive index.

I said Einstein may be wrong. I should have added that I don`t think so.

Best regards, Richard Harrison, KB5WZI

Or to put it in more realistic terms, as instrumentation gets better
and better, the value of c gets more decimal points.

By 1947 it was to +/- 3 km/s, in 1958 +/- 0.1, and by 1973 +/- 0.001.

To put things in perspective, +/- 0.001 km/s is an error of .000000000007%.

Actually, what he said was "God does not play dice with the world.".

He also said "Nature shows us only the tail of the lion. But I do not
doubt that the lion belongs to it even though he cannot at once reveal
himself because of his enormous size".

## 89. Owner's manual for the discontinued Radio Shack 15-1853 loop

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-03 22:15:00 UTC
From: usmcemen@hotmail.com
Message-ID: <81932e5c.0410031415.55e9ce73@posting.google.com>
Source record: 88783
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.antenna

Greetings, all--

I just purchased the very last in-store stock of the 15-1853 here in the DC area ($10 clearance) -- unfortunately, it was the store's old floor display model, which was missing its box, the manual, and the wire to run to the external AM and ground connections on the back of my new GE SRIII.

Since the 15-1853 has long since been discontinued, the Radio Shack website no longer posts the online version of its owner's manual, which I'm trying to track down (I need it for schematics and/or tips on the optimal cable I'll need to run from the loop to the radio, plus it's just my personal habit to always have owner's manuals around 'just in case'). I also tried the 'Wayback Machine' at archive.org to see if I could access the manual from earlier versions of the Radio Shack website, but no dice...

If anyone happens to have a copy of the 15-1853's online owner's manual on hand, I'd certainly be most appreciative to receive a copy via e-mail.

Many thanks!

- Cez.

## 90. Radial installation method

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-03 22:19:13 UTC
From: Mike Coslo <mcoslo@adelphia.net>
Message-ID: <lrCdne8ikY9A5_3cRVn-uA@adelphia.com>
Source record: 88784

I just got done installing radials for a new antenna, and was distressed at the amount of time it was taking.

I was looking at some power tools that might speed up the trenching process. Power edgers looked promising, but were 90 - 100 dollars for electrical models, and more for the gas powered ones.

Finally I hit on something. I bought an inexpensive electric chainsaw. I'm sure the neighbors thought I was a lunatic, but trenching for the radials took surprisingly little time. So I laid all my radials in one afternoon. It would have taken even less time if there had been an extra person around to help.

Caveats:

This is of course *dangerous* - don't ever do it!!! Chainsaws are sharp and nasty.

It wore out the Chainsaw chain. That really isn't a big deal. I'm just going to save it for the next time I need to trench radials.

The chainsaw needs washed and lubed after trenching.

But it was quick. The radials are in, the post for the vertical is in and concrete setting as I write.

Just thought I'd share this with the group. I never saw anyone else saying they did anything similar, so I either stumbled on something, or I'm completely whacked! ;^)

Just put it next to the SRIII at one end, with its axis aligned with
the long dimension of the SRIII. Tune for max noise at each frequency.

Put both radio and loop on a lazy susan, if you want more variation.

You won't notice much change at night, but there's a good deal in
the daytime.

Actually the loop works better (improves more) with a smaller radio;
the SRIII is already pretty good.

The loop is an impedance matcher. Once the radio is hearing propagating
noise (which the SRIII almost does on its own) further improvements
don't do you any good, since they would only enhance both signal
and noise. But until that, you're beating out internal receiver
noise by raising both external noise and external signal.

At night, you're hearing a thousand signals on every frequency,
so sensitivity isn't really the problem; and thus the loop doesn't
seem to be helping much at night. It's hard to tell it's even there.

I don't think that will work in my situation:

http://www.qsl.net/n7ws/N7WS_Vert_1.jpg

Eveything in the picture has thorns, spines, stickers or a rattlesnake
coiled up under it.

And yes, there are radials running under all of that stuff and I'm
standing over radials where I took the picture.

Quiz: How did I do it?

## 97. Reg's programs and Windows-XP

If your computer's operating system is Windows-XP some of you may have a
problem with running my programs full-screen. If so -

Right click on the program's Icon.
Click Properties.
Click Screen.
Click Full Screen.
Click Apply.
Click OK.

and all should be fine.

If you have a lot of programs in a common folder there appears to be no way
of changing all of them to full-screen simultaneously. You will have to do
it one by one. (Unless somebody can discover an easier way.)

I have two machines, Windows-98 and Windows-XP. If a problem should arise
with any other Windows versions please let me know.

Older cam corders worked in infra-red too. I have used this to find hot spots on PC boards. Sometimes the bad IC lights up like a light bulb. Same principal should work here. I understand newer ones are not IR sensitive. This is because people were installing IR filters on them and shooting pictures at the mall and work. Makes one look like they have no clothes on.

This is strictly a guess, but I tried the Hustler on 75 meters when it first came out back in the 50s. I quickly
developed the impression that the principal impedance matching device was the lossy coil. VSWR was good, signal reports
were lousy. Needless to say, I went back to a bugcatcher and a base matching coil.

The back is getting a bit sore as the evening wears on. I can only
guess that it would have been worse with the other methods form the time

I would have had to be bending.

One unexpected sore part is the fingers of my left hand got their nails worn down and the skin is tender now - kind of like when a person first plays the guitar. Probably from pushing and guiding the radial wires on the ground as I pushed them under. Gloves for me the next time!

it probably is not the cheapest, but http://www.andrew.com/catalog38/ has pretty much what's needed in the way of grounding kits and tower hardware.

most radio and TV stations seem have some of that stuff laying around left over from an install. odds and ends of hardware and clamps. got any buddies that are broadcasters?

Richard Clark wrote:
"Poe got it right."

I had no idea Poe had such a scientific interest. Poe no doubt got many things right but his observations on the universe are so extensive and written so long ago that it is unlikely that some errors can`t be found. Poe`s scientific study is impressive and he got right much of what he wrote. Where did I get the idea he spent much of his life spaced out on drugs?

In the years since Poe, much has been added to scientific knowledge.

The antenna section of "Transmission Lines, Antennas, and Wave Guides" by King, Mimno, and Wing, was written by Ronald W.P. King. On page 73 he gives the dielectric constant of free-space as:

Epsilon o = 8.85 times 10 to the minus 12 farad / m.

King also gives the permeability of free-space as:

Mu o = 4 pi times 10 to the minus 7 henries / m

From these, King calculates the velocity of light (vC).

vC = 1 / sq.rt. Mu o times Epsilon o = 3 times 10 to the 8th power m / sec.

On page 117, King elaborates, saying: The existence of a characteristic resistance for electromagnetic effects is just as mysterious (no volts and amps in the wave itself), but no more so than the existence of the finite velocity---3 times 10 to the 8th power m / sec.

---Physical science seelks to provide a mathematical mechanism for predicting observable effects about nature."

Best regards, Richard Harrison, KB5WZI

Apparently you have followed the link I've offered to Mike.

>Poe`s scientific study is impressive and he got right much of what he
>wrote. Where did I get the idea he spent much of his life spaced out on
>drugs?

Hi Richard,

This may be attributable to his contemporaries, certainly. After-all Coleridge and buddies tasted the popular social drug, Hashish.

However, Poe's "drunkenness" was a legend based upon his death, which recent theories dismiss through rather abstract research (and I am rather vague as to them myself, having seen them in fleeting reference some years ago). Either way, there is very little substantiation as to the cause of his death except he was found collapsed in the street. He died about a year after this work I have offered.

>In the years since Poe, much has been added to scientific knowledge.

Perhaps, but Poe's contribution is not from demonstration, as he would say, but rather through knowing the truth - an artistic intuition. His style directly attacks the notion of exactitudes, especially when they are eclipsed by later, more ponderous exactitudes. This is especially shown in his wry commentary through the fictitious future correspondent of the message in the bottle:

"'Do you know that it is scarcely more than eight or nine hundred years ago since the metaphysicians first consented to relieve the people of the singular fancy that there exist but two practicable roads to Truth? Believe it if you can! It appears, however, that long, long ago, in the night of Time, there lived a Turkish philosopher called Aries and surnamed Tottle.' [Here, possibly, the letter-writer means Aristotle; the best names are wretchedly corrupted in two or three thousand years.]"
...
"Well, Aries Tottle flourished supreme, until the advent of one

Hog, surnamed 'the Ettrick shepherd,' who preached an entirely different system, which he called the a posteriori or in ductive. His plan referred altogether to sensation. He proceeded by observing, analyzing, and classifying facts -- instantiae Naturae, as they were somewhat affectedly called -- and arranging them into general laws. In a word, while the mode of Aries rested on noumena, that of Hog depended on phenomena; and so great was the admiration excited by this latter system that, at its first introduction, Aries fell into general disrepute. Finally, however, he recovered ground, and was permitted to divide the empire of Philosophy with his more modern rival: -- the savans contenting themselves with proscribing all other competitors, past, present, and to come; putting an end to all controversy on the topic by the promulgation of a Median law, to the effect that the Aristotelian and Baconian roads are, and of right ought to be, the sole possible avenues to knowledge: -- 'Baconian,' you must know, my dear friend," adds the letter-writer at this point, "was an adjective invented as equivalent to Hog-ian, and at the same time more dignified and euphonious."

The style is rather dry and extended for modern readers, so I will offer a shorthand of this introductory matter that Poe offers. He is simply mocking the philosophers, Aristotle (Aries, the Ram) and Bacon (Hog, the pig), or rather mocking those who drag their corpses out to embellish their own impoverished theories (AKA, the "Transcendentalists" or our Hash eaters already mentioned):

"The error of our progenitors was quite analogous with that of the wiseacre who fancies he must necessarily see an object the more distinctly, the more closely he holds it to his eyes. They blinded themselves, too, with the impalpable, titillating Scotch snuff of detail; and thus the boasted facts of the Hog-ites were by no means always facts -- a point of little importance but for the assumption that they always were. The vital taint, however, in Baconianism -- its most lamentable fount of error -- lay in its tendency to throw power and consideration into the hands of merely perceptive men -- of those inter-Tritonic minnows, the microscopical savans -- the diggers and pedlers of minute facts, for the most part in physical science -- facts all of which they retailed at the same price upon the highway; their value depending, it was supposed, simply upon the fact of their fact, without reference to their applicability or inapplicability in the development of those ultimate and only legitimate facts, called Law.

"Than the persons" -- the letter goes on to say -- "than the persons thus suddenly elevated by the Hog-ian philosophy into a station for which they were unfitted -- thus transferred from the sculleries into the parlors of Science -- from its pantries into its pulpits -- than these individuals a more intolerant -- a more intolerable set of bigots and tyrants never existed on the face of

the earth. Their creed, their text and their sermon were, alike,
the one word 'fact' -- but, for the most part, even of this one
word, they knew not even the meaning.

A sweet vintage of writing that makes the grape pale.

## 109. Linear Loading Loop Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-04 05:53:30 UTC
From: theplanters95@aol.comnospam
Message-ID: <20041004015330.19211.00001959@mb-m03.aol.com>
Source record: 88803

The good news is that I have no antenna restrictions. The bad news, is that I am on a small lot. The best HF (75m-10m) fitting antenna seems to be a random length loop around the eaves of the house. Would it be better to linear load the loop? That is, instead of using a single wire to construct the loop, to use TV twinlead?

Or would a 2 or 3 multiturn loop be practical? That is run 2 or 3 turns of single wire around the house?

I am looking for a NVIS antenna for 75m and 40m and a dx antenna for 20m-10m. Power would be 100 watts or less. Feed would either be ladder line to an antenna tuner or ladder line to a 4:1 remote balun with a short length of coax to the antenna tuner.

Any suggestions or comments?

Randy Ka4nma

Uh oh; Cecil asks The Big One! A few of the answers are:

1. God?
2. God's not omniscient.
3. God takes long breaks.
4. God subcontracts.
5. Free Will isn't free, and the rent is overdue.
6. God likes dogs better than humans.
7. God's got a weird sense of humor.

Hi Mike

I just used a LARGE Butchers Knife (with addition) and a rubber
mallet.
The addition to the butchers knife was a U shaped steel tube welded to
the side to plant the radials at the same time the slot was cut.
No dirt to fill back in, and little to no visible damage to the lawn.
The rate of burying radials in this fashion was faster than 500 ft per
hour.

Yes we love it here, but I'm a desert rat and grew up in the area. I
did have one case of RFI when I was running max smoke on 2-meters and
getting into everything in a neighbors house. I copied the FCC's TVI
handbook for dummies and stuffed it in his mailbox. Never heard
another word. I think he must have found a "diode" junction in his
electric fence because he didn't complain anymore and I didn't hear
his fence anymore.

The secret to installing ground radials through (under) cactus, Palos
Verde and ironwood trees without getting stuck is to use a "needle and
thread" method.

The needle in this case is a 20' length of 3/8" rebar and the thread
is the wire. A hose clamp attaches the wire to the rebar. The rebar
is limber enough to deflect around small obstacles (roots) yet stiff

enough to penetrate loose earth. Needless to say, the wire isn't buried much, if at all, but there's not much foot traffic through these areas.[g]

;-) You just aren't working with small enough, high enough frequency
circuits, Reg.

3 turns of 28AWG on a 4-40 (USA) screw (remove the screw, of course)
will give you about 18 nH. Unloaded Q at 440MHz will be around 200.
>
> The link to the schematic is:
> http://www.radiotronix.com/downloads/433_pair.pdf

Easy enough to use SMT components soldered to a piece of copper-clad
for a ground plane. Just put down the two caps and the shunt resistor
"tombstone" style, one end soldered to the ground plane and the other
up in the air, separated by enough distance to put the series coil and
resistor between them. You can keep the parasitic L and C very low
indeed this way. You can also use tiny squares of copper-clad glued
down to the ground plane as tie points.

It's also possible to mechanically make a simple circuit like this on
copper-clad using surface mount parts, by scribing lines with
something like an X-Acto knife and removing strips of copper. In this
case, I could see scribing four lines across the board, separated by
about 1/16 inch, and removing two copper strips, one from between the
first and second scribe, and one from between the thrid and fourth
scribe. That leaves a trace about 1/16 inch wide. Cut gaps in the
trace, about 1/16 inch long, where you want to solder down series
components. Solder shunt components across from the trace to the
copper ground plane. Bridge across the trace with a copper strap to
connect the two gound plane sides, with the bridge up in the air over
the trace. Nice to have a ground plane on the opposite side, with
some holes and wires to connect to the top-side ground planes, but not
necessary. I'm thinking 0805 parts with the sizes I mentioned...make
things slightly larger for 1206. You can make the trace be a 50 ohm
transmission line if you want, by sizing things right.

Cheers,
Tom

## 121. Windom vs G5RV : 1-0

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-04 19:58:59 UTC
From: Thierry <->
Message-ID: <4161ab85$1@news.vo.lu>
Source record: 88815

FYI.
Hi,
I come back with my 40m long Windom vs. my 31m G5RV question of 2 weeks ago.

I did my tests during 3 days from 10 am to midnight. How does the Windom perform ?
Theoretically the Windom is know to perform better (at least +1 S-point say some readers) than a dipole due to the mix of horizontal and vertical polarization, with the advantage of showing a more or less omnidirectional pattern.
http://www.astrosurf.com/lombry/Radio/ant-carolina-windom-radiation-pattern.gif

However some models cannot be tuned on WARC bands. Mine could be tuned on all bands with a SWR at the antenna below 2:1. At last, drawback, the Window radiates along its coax. On mine, only 30 cm where inside the shack, the remaining coax running outdoor, along the external wall of the house and between trees up to the feed point 7m high.

Two images for those who don't know this well-known antenna:
Windom design : http://www.astrosurf.com/lombry/Radio/ant-ocf-windom-dwg.gif
Installation of the windom sold by wimo.de :
http://www.astrosurf.com/lombry/Radio/windom-balun.jpg
Ends were attached for one in pines 8m high, the other on the chimney 7m high.

And indeed, I confirm the general opinion. The Windom radiation pattern is much more omnidirectional than the dipole one and I don't have noticed more QRM.

From what I have experimented from 160 to 10 m, including WARC bands, working in SSB I received better signal reports with the Windom and I confirmed countries I was never able to reach with the multi-band dipole.

Tight in the E-W direction, from Europe working on 20, 17 and 15m bands during 3 days I reached without much difficulties and often almost at first call North america (VE, K), South America (HK, YV, PY), Middle-east (9K, A4, A9, YI), Asia (4S, JA) and many VK stations.

Globally working bare foot with 100 W PEP, I had a SWR between 1.5-2 (quite high) but DX signal reports were between 55 and 57, often stronger on the axis 9K-4S-VK (and unconfirmed to UA9/0 due to lack of DX stations from these areas, but most UA1/3/4/6 arrived 59).
It is however more strange to note that the signal that I received was most of the time (say maybe 7 times over 10) about 1 or 2 S-points weaker than the strength of my signal to the DX.

But moderate this result. Of course with 100 W in a fixed wire antenna tight between 0.4-0.5-lambda high the configuration is far to be optimized. Then there were many DX (VR, XW, XU, etc) I was unable to work due to pileups. But results exceeded my expectations and I found signal reports quasi on par with a long vertical cut at L/4, but without QRM, a really mix of performances of a dipole and a vertical.
NB. Of course there could be a drawback if you use high power (> 200W) due to RF radiation in the shack. This can be avoided using the Carolina design.

For short, I kept the Window, and sold my G5RV ! I will mainly use it on low bands.
And thanks to OMs who read this thread and who permitted me to test this antenna on the air; your QSL is already sent ;-)

Hope this helps.

## 122. Coaxial folded dipole (was: Natural balun/Antenna on 9/26/2004)

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-04 20:19:41 UTC
From: John Smith <kd5yikes@mindspring.com>
Message-ID: <cjsb8u02g8p@enews1.newsguy.com>
Source record: 88816

Okay, then, I will present data measured this day for this antenna:

http://www.sophisticatedsolutions.us/images/Folded%20Dipole.jpg

This is shown in "Antennas for All Applications" on page 820, figure 23-17 (a).

I built the antenna wholly from RG58. The center conductor of the right half is not connected at either end. It is 14.375 inches wide and averages a little less than .5 inches between the centers of the top and bottom conductors. Where the coax is shown exiting the antenna, is a female, flangeless, chassis mount, BNC connector so that I can replace the antenna with a short.

My test set up is a VHF oscillator, a vector voltmeter, and a Narda dual directional coupler. I use a 66 inch piece of RG58 from the output of the directional coupler to go to the antenna. The short circuits I use are the best I could make from BNC connectors. The 50 Ohm load I used for comparative measurements is one of those used for network terminators. Yes, I am aware they are not instrumentation quality, but it's what I have.

For a given frequency, I replace the antenna with the short and adjust the amplitude of the oscillator and the controls of the vector voltmeter so that the reference channel (A) is 10 mV and the phase is 180 degrees. I record channel B's amplitude. I then remove the short and connect the antenna. I then read and record channels A, channel B, and the phase. From these data I calculate the impedance (per HP's AN 77-3, thanks to Wes Stewart).

The first item measured is the 50 Ohm terminator. I also measured it at the conclusion of the tests to see if there were any differences and there were none.

Here are the results computed from the data:

Freq (MHz) Impedance (Ohms)

410 46.4 + 6.0i (50 Ohm terminator)

380 9.7 - 12.5
390 3.5 - 5.7
400 5.1 + 1.3i
410 5.1 + 6.5i
415 4.0 + 10.0i
425 2.5 + 15.7i

This is surprising to me and doesn't make a whole lot of sense. For one thing, I would have expected the impedance to vary wildly over the range shown. For another, the low impedance seems, well, really low.

Is the trend of the data as shown to be expected? Well, maybe the reactive part? The real part seems to make a little sense except at the extremes.

Can I trust this data to be even approximately right? I mean, can I now say that the antenna in question is maybe nice due to the natural balun but I might as well forget it as a simple antenna because to the low impedance?

Or, should I say this is utter nonsense, the antenna is probably okay, it's just my equipment, setup, or lack of knowledge giving erroneous data?

Your opinions are welcome.

John (KD5YI)

John,

First of all you are to be commended for running these experiments.
Without a bit more study of your situation I can't comment too much
but I wanted to throw out a couple of quick ideas.

1) Do you have the VVM probes terminated in 50 ohm?

2) If you don't have the line stretcher as in Fig 7 of the note, are
you recalibrating at each test frequency?

3) How well is your signal source terminated, in other words do you
know its source match?

Each of these things can affect the outcome.

More later,

Wes

I only know that the signal source is an HP 3200B. It directly feeds the
Narda dual directional coupler through a few feet of RG58.

Hi John,

How about the raw data? How about a detailed description of the NARDA coupler? It should have a calibration plate affixed to the side of it with freq vs. coupling marks (generally pretty close).

I would note you have a considerable SWR, but this was expected going into the test (however, in an inverse proportion, which may be meaningful here).

|> know its source match?
|
|
|I only know that the signal source is an HP 3200B. It directly feeds the
|Narda dual directional coupler through a few feet of RG58.

If I remember that correctly the '3200 is nothing but a p-p oscillator
and a waveguide-below-cutoff probe. If your VVM reference probe
readings are changing much between frequencies and/or
calibration/measurement, try a 6 or 10 dB pad right on the generator
```

output and see what happens.

When you're calibrating using a short, the source Z has really got to be nailed down.

Wes

John,
Discounting the absolute values, the numbers seem to make sense, except for the 9.7. Might it have been 2.7? There seems to be resonance at around 400. The impedance goes more reactive in both directions from there, and the real part goes down monotonically, except for the 9.7

I looked at the picture, and it is not 100% obvious to me what gets connected at the balanced point. Just for kicks, I am going to try that, somewhere within the range of an MFJ269.

The 3200B is the oscillator they use in the HP AN 77-3 you sent to me. I'm using it the same way they did except for the stretcher and a Narda (rather than HP) coupler. However, I'll try to run a test and determine how much difference there is using a pad.

The Narda coupler has no calibration plate. It says model 30611, serial no. 4235. It also appears to have been made for Motorola, as their part number appears on it. One end says "BTS" and the opposite end says "ANT". At the BTS end, on the side, there is a connector which says -30 dB. Similarly on the antenna end.

Raw data:

Reference Measurement
Freq A1 B1 ?1 A2 B2 ?2
415 1 0.76 180 0.82 0.535 158
410 1 0.77 180 0.905 0.57 165
400 1 0.79 180 1.08 0.695 177
390 1 0.81 180 1.02 0.72 -167
425 1 0.743 180 1.06 0.72 145
380 1 0.815 180 0.86 0.485 -151

Hi, Tam -

I will try to repeat the test at that frequency.

By the balanced point, I assume you mean at the bottom center. It is a female BNC connector, facing downward. A halfwave length of RG58 goes off the left side and folds. The coax is soldered in normal fashion to the connector. Another halfwave piece of RG58 goes off the right side and folds. The center conductor of the right side piece is not connected on either end. The shield of the right side coax is soldered to the shell of the BNC and the two pices of coax is joined as shown in the figure.

If by the balanced point you meant at the top center of the figure, the center conductor only of the left side coax is soldered to the shield only of the right side coax.

If this description is not clear, let me know and I'll try again. I would take a picture and make it available, but I'm afraid it would only confuse due to lack of detail.

Thanks,
John

Well, measured again, at 380 MHz I get 0.9 - 4.4i.

Okay. I repeated the test using an HP 355C attenuator set for 10 dB and at 400 MHz got 4 + 3i on the antenna. I also checked my 50 Ohm network terminator with this setup and it measured 44 + 4i. The data are different, but they're not an order of magnitude different, at least.

So, although my measurements aren't repeatable, they are sloppily consistent. That is, although I can't say exactly what the antenna impedance is with confidence, I am beginning to believe that it really is very low in impedance. Am I drawing an erroneous conclusion too early? I can wait a little longer to draw an erroneous conclusion.

John

John, This turned out simpler than I thought. I did a quick and dirty test
with a folded dipole made up of two 3 foot pieces of RG58, and a feedline
1/2 WL at 160 MHz. Unfortunately, this puts me too close to the upper limit

of the MFJ, but you can see what happens. BTW, I meant the top for the balanced point. Turns out it makes no difference whether the center conductor of the left side is connected to the center conductor, or the shield, of the right side.

My numbers:

F R X
145 30 89
150 10 60
155 ? 7? 14? This looks like 165
160 8 25
165 7 13
170.25 6 0
175 5 14

I would say that if anything, my numbers make less sense than yours. I also got a reading of 1+j0 at about 65 MHz. Don't know what that means, other than a dead short. I will hook it up as a regular folded dipole, and see if I get anything like 300 Ohms. Probably tomorrow.

Was this claimed to be a 50 Ohm antenna?

Tam/WB2TT

Hi John,

This is not a NARDA model number according to their own catalogue,
although I see it described as NARDA in more than one ebay auction. I
would say this is a special run for Motorola (which is probably their
contract number with NARDA).

However, all ebay auctions list this as an 960 MHz device.

Typically, directional couplers are within their nominal ratings only
over a octave range and some of those octaves from within their
catalogue are 500 MHz to 1 GHz. Others are 450 MHz to 900 MHz. Some
are listed as 0.05 GHz to 1 GHz, but the coupling is VERY MUCH
different than nominal outside the octave range (by as much as 10 - 15
dB). Generally, you don't suffer this much variation near the octave
band edges, but they do track off from their otherwise flat response.

It looks like you need to measure the coupling directly (at both
ports) across your frequencies of interest. The coupling factor is
not so important as is the ports tracking. I will discuss the raw and
finished data separately.

Hi John,

Well, from the two results above, and referencing my copy of Appl.
Note 77-3, Page 7, section "Measuring Rho 100 to 1000 MHz," there are
a number of issues here.

Your B1/A1 is quite off the mark (but certainly correctable, afterall,
that is the purpose of its measurement).

|Rho| = B2ï¿½A1/A2ï¿½B1 = 0.695ï¿½1/1.08ï¿½0.79 = 0.815

Casting the magnitude and angle onto a Smith Chart would suggest your
5.1 + 1.3i Ohms is close enough given your data.

The only kicker is port tracking, but I have a hunch that probably is
not an issue.

This bears further consideration. Too bad Kraus did not choose to
elaborate.

>(a).

Just an off the cuff remark and a possible clue.

It's not clear from the picture or explanation if the center
conductor is continious from the right half of the antenna to the
left. I understand the center conductor does not connect to the
right half at the T.

For the case that it does continue:
Looking that the picture, if the right side were parallel to the left
I'd call that a 1/4 wave 1:1 balun with a shorted load connected
rather than an antenna. That would result in a significant reactance
or a short depending on frequency. The sorted load would be the
continued centor conductor in the right half.

For the case that it does Not continue:
I'd call that a 1/4 wave 1:1 balun with an open load connected rather
than an antenna. That would result in a significant reactance again.

There is a third case:
A connect dot is missing at the junction of the center conductor where
it meets the shield of the right loop (top center). If the lengths
were ~1/4 wave for each side then the impedence at the center would
be high for the left center conductor and the right shield and that
would likely be a tuneable folded dipole.

Did I miss something about the antenna design?

As drawn it looks like an attempt to take a parallel line balun (coax
with a 1/4wave 1:1 balun) and make it serve as a radiator. There is
detail missing one possible dimensions and other connections.

FYI: if you used one of those cheap eithernet Tees to create the
junction, I've found them to be very poor at UHF. Use a good quality
one with TFE insulation and test it seperately first.

Allison

The center conductor in the right half is not used at all. The right half
should actually be a piece of coax with the center conductor removed.

The center conductor of the left side is connected to the shield of the
right side. The shield of the left side is not connected at the top center.

I wound up not using a T. I simply soldered all connections to a BNC
connector at the bottom center of the figure.

John

Hey, Tam!

This is great information! According to the dimensions, it should be resonant at 173 MHz. (Close enough... I subtracted 1 inch on each side for the loop). Your 6 Ohms is close enough to my 5 Ohms to satisfy me that I'm not getting useless measurements.

I wouldn't worry about the 65 MHz reading, as that's so far away from resonance that it is probably acting like a shorted half wave transmission line or some other kind of crazy network.

No, there was no statement given about the antenna impedance. That's why I started this thread. I was interested in the antenna because:

1. It is at DC ground.
2. It is a half wave, giving a nice omnidirectional pattern if mounted vertically.
3. No balun is needed as it is inherent.

However, it appears to be not worthwhile after all, owing to its low feedpoint impedance.

I really appreciate you taking the time to perform your experiment. I'm now convinced that the antenna is next to worthless.

Thanks,
John

I don't understand. Please enumerate the issues. What do you mean B1/A1 is off the mark? If they are off the mark, how can the Z be close enough?

Are you saying that I have calculated the Z correctly from the data and you think port tracking is not at fault? What further consideration?

You're right. Too bad Kraus didn't tell the feedpoint impedance. I suspect I would not have embarked on this folly if he had. The antenna may have its uses elsewhere, but I don't need the headaches of matching 5 Ohms at 440 MHz.

John

## 142. Xerox TDR ??

I just got a Xerox Digital Time Domain Reflectometer Model 600T80024. It's an 8"x9"x3" black plastic box with a LCD readout and 12 digit keypad for programming, and 3 BNCs for input, output for a scope, and sync. A 4 position rotary switch for off, 50 ohm, 75 ohm and monitor. It looks like the cable type and velocity factor as well as other parameters such as meters, feet, or nanoseconds can be programmed. It's portable,battery powered and on powering the LCD indicates XEROX 1985. It seems to work but I get an ERROR indication most of the time because im hacking and don't know what I 'm doing without basic instructions. No luck with Google or xerox.com, xdss.com or their 800 number. Any tips or leads on how to run or program this thing appreicated.
tnx

Hi John,

You should get 1.0 @ 180ï¿½ (the definition of a short).

> If they are off the mark, how can the Z be close enough?

Because what you DID measure, was used as a correction factor per:
|Rho| = B2ï¿½A1/A2ï¿½B1 = 0.695ï¿½1/1.08ï¿½0.79 = 0.815
(or you skipped that step)

>Are you saying that I have calculated the Z correctly from the data and you
>think port tracking is not at fault?

Well, that is really your job to confirm or deny. There is very
little I can accomplish short of that.

>What further consideration?

I suppose I could visit my Engineering Library. I will be on campus
for my Nanotechnology seminar today anyway.

Well, that's not possible when feeding a length of RG58 at 400 MHz, is it? Remember, I said that there was about a 5 foot length of RG58 between the directional coupler and the load. How can one get 1.0 reflected to the coupler when the load is a short? That requires zero loss coax.

I did that. As far as I can determine, I did it like the HP application note said to do it.

Thanks for your comments.

John

## 145. Re: Coaxial folded dipole (was: Natural balun/Antenna on 9/26/2004)

John,
I had breakfast with some friends this morning. One of them has a PHD in EE, specializing in antenna design. He thinks the antenna should work, but suggested changing the spacing between the upper and lower conductors. He also told me to look for multiple resonances. I just now tried that, with the spacing essentially 0. What I got was a new resonance at 165 MHz, with Z=18 + j0. . Interestingly, I now seem to have hit parallel resonance, like you did, and R goes down either side of 165. In fact, accross 100 -150 MHz the Z is 0 -jX. When I was messing around with spacing, at one time I got 202 + j0 at 129 MHz; but that is way off calculated frequency. I probably should not be doing this inside, as it is not entirely repeatable.

I also tried a longer piece of coax (RG8X, Vp=.75) that gave me a 5 foot folded dipole. That should be resonant at about 93 MHz. I clearly got multiple resonances:

F R X
92.5 3 j3
100 11 j44
110 80 j181
120 4 j30
127 4 j1
160 53 j14 SWR=1.3
170 11 j0

The feedline was also 5 feet, since I did not know what a wavelengt was going to be. This looks like it wants to be a 160 MHz antenna, instead of 93. Lastly, I tried the 5 foot antennawith a 2 inch feedline.Resonance was at 156 MHz. If I get a chance, I will try it outdoors tomorrow.

Tam/WB2TT

Sounds like the one I have, but mine's called a LANCA DIGITAL TDR.
No other info. Possible that it was marketed under multiple names.
Holler if you find anything.

<http://support.radioshack.com/productinfo/DocumentResults.asp?sku_id=15-1853&Name=Manuals%20for%2015-1853&Reuse=N>

Shows owner's manual in English and Spanish, plus other doc
and a parts list.

When in doubt, just put the catalog number in the search box.
This one went direct to the support docs due, I guess, to the product
itself being out of production.

And the groove in the bar may be more V-shaped than when you
started. I once used a friend's well-used chainsaw and the chain could
wobble a bit in the groove because it was no longre a parallel-walled
groove. Not sure if this makes it easier for the chain to jump out. I
didn't use it for long.

On the RS website, their search engine seems to differentiate between
catalog numbers WITH a hyphen (15-351), and those without (15351).
This is different than many other search engines, where looking up one
will find both versions.

I would suggest entering it both ways to do a complete search of the
RS archives.

|>
|> Wes
|
|
|Okay. I repeated the test using an HP 355C attenuator set for 10 dB and at
|400 MHz got 4 + 3i on the antenna. I also checked my 50 Ohm network
|terminator with this setup and it measured 44 + 4i. The data are different,
|but they're not an order of magnitude different, at least.
```

|
|So, although my measurements aren't repeatable, they are sloppily
|consistent. That is, although I can't say exactly what the antenna impedance
|is with confidence, I am beginning to believe that it really is very low in
|impedance. Am I drawing an erroneous conclusion too early? I can wait a
|little longer to draw an erroneous conclusion.

First of all, neglecting the feed method, the antenna is a simple folded dipole. In free space, or an approximation thereof, it should have a feedpoint Z of about 300 ohm. (See the ARRL Antenna book for a description of why this is so under "Special Antenna Types", p.2-32 in the 17th edition) In the presence of other (non-resonant) objects, it may differ from this but not a whole lot.

In theory, the "natural balun" doesn't change the impedance of the feedpoint whatsoever. By "feedpoint" I mean the gap between the ends of the folded element, not the "tee" connection opposite.

At the outside of the tee connection, the voltage is zero thus this point can be grounded, connected to the boom in a Yagi, etc. without upsetting anything. Likewise the coax feeder can be introduced here and run through one side of the element without upsetting anything either.

But, a nominal 300 ohm load is terminating a 50 ohm line, so the usual transforming effects are in play. The input Z of an arbitrary length line is---well, arbitrary. If the line is many wavelengths long, then when the frequency is changed, the long lines effect kicks in and the input Z is going to vary rapidly with respect to frequency.

Second. I believe that you need to determine the parameters of your directional coupler. As Richard pointed out, your B1/A1 numbers are pretty unstable.

So here's what I recommend. First verify that the "A" and "B" probes read the same thing when connected to the same source. Then put your pad right at the input connector of the coupler. Terminate the reverse port and connect your VVM "A" probe to the ouput connector and the "B" probe to the forward port.

The ratio reading is the forward coupling factor of the directional coupler. Vary the frequency and see how this changes and note some values. Move the "B" probe to the reverse port and terminate the forward port. Note the readings at the same frequency.

Reverse the input and output ports and repeat the measurements. Ideally, the data sets will track closely. If they don't then you have a problem. Serious differences might indicate damage to the internal terminations. This assumes that this is a true dual coupler and not single line coupler with the termination applied to the unused port externally.

If the numbers are consistant, then you can determine the directivity by computing the ratio between the two readings on a given port when the coupler is reversed.

I'm going to stop here and assume you understand the consquences of poor directivity on measurement accuracy. If you don't then I can expound further later.

Wes

I put the oscillator to the center of the HP Power Splitter. I then put a
probe tee on each of the splitter outputs followed by a 50 Ohm terminator.
The difference between the A and B channels was maybe a needle's width.
Reversing the splitter made no difference. Swapping the terminators made no
difference.

> Then put your
> pad right at the input connector of the coupler. Terminate the

From 350 MHz to 450 MHz the forward port coupling was -25.9 dB to -26.2 dB.

> Reverse the input and output ports and repeat the measurements.
> Ideally, the data sets will track closely.

I got the same here within about a tenth of a dB.

Hi John,

As Wes suggests, butt up the load against the directional coupler
output and eliminate this arbitrary loss of the 5 foot RG58. It
should also shift the readings too (you are simply walking around the
circle of constant SWR). One question that would be obviated in this
process (but I have to ask anyway) is WHERE was this short you
applied? At the output port of the coupler, or at the end of this 5
foot RG58? (Same question applies to the calibrated load).

The other measurements that you reported in response to Wes indicate
you have tracking ports (even if they are off by 4dB). As I said, it
seemed unlikely this would be a problem and it confirms the
out-of-octave specification.

Do what? They are both -26.2 dB. I don't understand.

John

I used a 66 inch piece of RG58 between the directional coupler and the load.
It was at the load end of this piece of coax that I calibrated with a short
and made the load measurements.

Hi, Wes -

I read a little about directivity (a little was all I could find). Tell me
if I measured it correctly...

Forward directivity:
Normal setup, ie coupler in the usual direction (forward). Best 50 Ohm load
I could muster on the antenna (output) terminal of the coupler. Set channel
A for 0 dB. Channel B reads -29.2 dB.

Forward Open/Short characteristic:
Remove the 50 Ohm load. Set channel A for 0 dB. Channel B reads +.4 dB. Put
the HP calibrated short on the antenna terminal. Set channel A for 0 dB.
Channel B reads -1.2 dB.

Reverse directivity:
Reverse the coupler. The antenna connector now has the oscillator applied.
The BTS terminal has the 50 Ohm load. Set channel A for 0 dB. Channel B
reads -23 dB.

Reverse Open/Short characteristic:
Remove the 50 Ohm load. Set channel A for 0 dB. Channel B reads +1.1 dB. Put
the HP calibrated short on the BTS (now the output) terminal. Set channel A
for 0 dB. Channel B reads -.5 dB.

So, in the forward direction, the directivity is -29.2 dB, and in the
reverse direction, the directivity is -23 dB. Yes?

What do I do with these results? I don't know how to apply them even though
I read the HP paper.

Thanks.

John (KD5YI)

By the way, if you (or anyone else) need to contact me via email, you can omit the kes in the address.

## 164. Looking for ant measurement software/hardware

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-06 02:27:55 UTC
From: Mike <km6ab@pacbell.net>
Message-ID: <LKI8d.7251$nj.5419@newssvr13.news.prodigy.com>
Source record: 88759

I am looking for advice in choosing an economical antenna turntable and software package for analyzing antenna patterns on small microwave dish antennas. I have RF sources, reference horns and HP Spectrum Analyzers available as well as HP Vector Network Analyzers. I have seen software used in the past that runs an HP Spectrum Analyzer for collecting data. The software was geared towards the satellite industry where the antenna positioner was run separately from the data collection software, which allowed you to enter the speed of the positioner and the spectrum analyzer sweep speed was matched to the positioner speed and amount of rotation. The software also centered the peak of the beam on the plot and allowed you to fiddle with parameters. I am considering using a Daedal precision turntable as I only need azimuth cuts up to 180deg, but would like to know if there is a specific industry accepted positioner that is cheaper. I am also having trouble locating data collection software as I described. I found a company that has a software/turntable system, but itï¿½s a bit overkill at $18k. There must be something that will do a satisfactory job at a cheaper price. Any comments?
TIA,
Mike

Hi Tom,

Being so new at this, I don't even know what you mean by 'tombstone style', and it sounds like an awful lot of work to be scoring pcboard with an Xacto knife to create transmission line effects.

I talked with a tech rep from radiotronix today. They called me because I ordered a half dozen modules from mouser. He explained that the pi circuit on the TX is so the TX sees 50 ohms, which is pretty critical. I have not done anything with the transmitter modules yet (they are from Velleman because they are thru hole), but I am building a receiver board on pc board using pcbexpress and single sided copper pcboard. It will be the first prototype. Now that I have it working on a breadboard I am going to build one and see how it works. I am planning on using a straight piece of (20ga) wire for the 18nH inductor and using the T network of 2 8pf caps beside it. The tech said this is just a low pass filter, but it seems to make a difference in receiver sensitivity. The noise on the receiver is supposed to be there according to him. It is between 1Khz and 1.5Khz. he said some people use the data slicer pin with a holtek ht12D decoder, which i am doing or you can also use a micro to look for the bit pattern and decode the signal. I am just using the TV (transmission valid) to set off the rest of my circuit which, right now, consists of a latch and an LED.

Joe

I used Daedal for Antenna turntable - it was in order of $5k, - turntable and controller, worked good for me.

Daedal came with brochure listing controller commands for serial port; 2-3 letters each. The rest you can write yourself - HPIB code and graphics. You would need HPIB interface for data collecting PC.

Andrey

You can easily build what you need using single-sided board: a continuous groundplane, components soldered on top, and connections made using sticky-backed copper tape (available at craft stores for stained-glass work).

If you cut strips 0.1in wide, these will be a good approximation to 50-ohm microstrip, for the relatively low frequencies and short lengths that you will need. On the reverse side, use broader the copper tape to link the groundplanes of your extension and the Radiotronix module.

Simply lay the SMD components against each other, and solder them together... but before you do, mark where the connections through to ground will need to be, for the two capacitors in the pi-network and possibly other places. Then drill the board and insert links of thick wire (14AWG) so that the ground connections will have zero length beyond the thickness of the board - but I really do mean ZERO, or else your network will not perform correctly. The ground links must be touching the ends of the capacitor chips before you solder them.

Likewise, use ZERO lead lengths inside the pi-network. Butt the ends of the two Cs and the L chips directly together, and solder. Any "connecting leads" must be restricted to the places that can use 50-ohm microstrip.

This construction method is very quick and simple. The SMD parts are well-enough anchored to the board for all normal conditions of use.

>I talked with a tech rep from radiotronix today. They called me
>because I ordered a half dozen modules from mouser. He explained that
>the pi circuit on the TX is so the TX sees 50 ohms, which is pretty

- so remember what I just said about zero lead lengths.

>filter, but it seems to make a difference in receiver sensitivity.

On the face of it, this pi-network has a 1:1 impedance transformation (two equal capacitors) so it shouldn't make any difference. However, there may be stray capacitances and/or inductances in the module that we don't know about. Bottom line is, this network is what the Radiotromix techs have found to work.

Since you don't have the design experience and the test equipment to measure how the whole thing performs, you would be very wise to copy EXACTLY what Radiometrix did, which includes building the whole network using the best possible construction practice.

Also, a straight piece of wire is actually a short length of transmission line: it does not have quite the same electrical properties as an inductor. So use an 18nH chip inductor like Radiometrix said.

This is really part of your "contract" with the module manufacturer. It isn't fair or reasonable to expect their tech support to second-guess what the effects of every individual user's network might be, if they're all slightly different. You might get away with it this time, but some of the worst tech-support problems are caused by people who declare:

"I did exactly what you said..."

[Now follows 20 minutes of intensive cross-examination over the phone]

"... oh, apart from all these things that are different."

[Deleted: strange sounds on the phone line. The tech has the curly cord gripped in both hands. He's puling it out straight, and he has a red glint in his eyes. Be very thankful that you're several hundred miles away...]

Sorry, that wasn't quite clear (not enough coffee yet this morning).

The continuous groundplane is on the underside of the board. All the SMD components are on the bare fibreglass side. The SMD components are held in place by soldering them directly to each other, to the ground links, to the striplines, and to various other fixed points.

No board etching is required, and this technique will is good to frequencies well above 1GHz.

The 0.1in stripline width was for standard 0.064in FR-4. You can obviously refine that calculation if you want, but there's little point for this particular application.

Tombstone style...just solder one end to the copper-clad board, and
the other end sticking up in the air. Looks like a micro-size
tombstone sticking up from the board.

...

It's really not all that difficult. Just use a ruler to guide the
knife, use a sharp knife, and the strips you want to remove can
usually just be pulled up in one piece (each). Or do it as Ian
suggested, with sticky copper tape.

As Ian wrote, keep lead lengths extremely short, like "zero." He
suggested putting a piece of heavy copper wire through the board where
you want to connect to the ground plane. Another way is to simply
drill a hole through the board and drop an 0805-size surface mount
part into the hole, and solder both ends. A 1/16" hole would work,
but you'd do better to pick a size that just fits the part you want to
use. Not all 0805 parts are quite the same size, but the body lengths
are pretty accurate and work nicely in 1/16" thick board material.
Any of the methods mentioned by Ian and myself will work well, and all
are reasonably easy to implement with a bit of practice and patience.

Cheers,
Tom

One method of "etching" that worked for me was using a reamer
bit on a drill press to cut through the copper and barely into
the PCB material. This has the advantage of leaving a ground
plane in between the active traces. Also great for scouring
and sizing PCBs.

I vote WHACKED(LOL)
You were on the right track when you were thinking edger. Rent dont buy,
cost about $20 for a half day. Got my neighbor to go in with me. Edged his
driveway and curb and mine and cut a trench for his low violtage lights.This
all took an extra 30 minutes. He paid the whole $20.

Source record: 88770

The objective is to get a sufficiently high value of impedance. It doesn't matter whether the impedance is inductive, capacitive, or resistive. You'll get the highest impedance at resonance, so that's the best choice for a single band and there's no point in modifying the design to "be sure it is on the inductive side". Typically, the impedance is higher even considerably above resonance than it would be with an inductive choke of fewer turns. With HF air-core coax chokes, the impedance is very high at resonance and on the bands immediately above and below the resonant band -- and adequately high for some or most applications at frequencies above and below that, since the resonance is quite broad.

Source record: 88672

I have an antenna and tower package on e-bay. It is a Universal 40-foot aluminum tilt-over tower (rated at 15 sq ft at 80 mph), including the rotator shelf. The antenna is a Cubex 2-element 5-band quad, with the a new set of wire elements still in the shipping box. Separate feeds are used for each band (20, 17, 15, 12, 10 meters) and an Ameritron 5-way remote coax switch is included. The rotator is a Yaesu G450A. Cables for the coax switch and rotator are included and are about 125 feet long.

Everything is included except the concrete stubs for the tower and a coax feed.

All are in excellent condition. Pick up only. Poughkeepsie, NY area. Anyone is welcome to inspect the set. Everything is on the ground (or in the house).

There are many "watchers" for the auction in e-bay, all waiting for someone else to make an initial bid. I hope the package goes for about $1300. Search for "tower" and "quad".

The quad is a great antenna. I went from 100 to about 275 confirmed in two years of casual operation. I am not quite as young as I was a few years ago and the handling of the quad (which is a large three dimensional structure) on a tower (which I no longer want to climb) is best left to someone a little more agile.

Not used, but I have seen them. Arguably the most attractive antenna out there. i hop

> With plenty of idle time to spare they are just repeating old wives' rumours
> for a little mischievous amusement.

I've read a fairly in depth report on one of the EH antennas. They said it worked. And the feedline radiation seemed to be what made it work. I haven't used a backpacker, but their work looked good enough to give it some credibility.

What do you think about the information that they publish

http://www.rayfield.net/isotron/isohow.htm

Claiming the transmit performance is the same as a half wave dipole, and the noise on receive is 3 db down from a half wave dipole? This would seem to indicate that the Isotron is a *superior* antenna as compared to a dipole. They don't mention anything about radiating feedline. So okay, maybe the feedline doesn't radiate.

Its *hard* to imagine why anyone would use anything else!

The isotron design is low efficiency, approximately 2-15%, depending on the frequency/model you have. Efficency isn't everything though in real antenna systems:
It approximates a point source in a highly multipathed environment. Therefore there are positions of placement/times where the antenna is in a gain-volume (as opposed to a null-volume) from the multipath. Ergo it will have a measureable dBm approximating a dipole in the far field. This is a transient effect and depends on ground; environment; and height.

However, there are times where an isotron can be placed quite high, whereas the phase center of a dipole cannot (because the dipole is much bigger; bulkier; unsightly.) Then the enhancement over higher ground can give a seeming approximate equality or advantage over the much lower dipole.

In true free space, the isotron is a mediocre/poor antenna, in my opinion. In real environments, it does have a useful niche, especially if you do 30, 40, or 80 M and can get it 50 or more feet up. There are reports of folks who put isotrons on top of apartment buildings and really kick butt. I doubt they win contests, but I'm sure they have a good time!

I have never seen anything deceptive in isotron's ads.

Assuming it's aluminum, I like Brasso. Or just 3M pads with a good rinse.

A 3M pad was worth about .4 dB on a range for me once at 432Mhz on a
17dB antenna. The antenna had been outside for about 2 years in MN.

## 185. High Efficiency Mobile HF Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-07 04:46:21 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <4164C962.6EE447@rickfrazier.com>
Source record: 88680

Looking for suggestions for a high efficiency mobile antenna for HF.
I'd like to be able to cover 80-10m, and don't mind stopping to change
out sticks to change bands, so long as I don't have to retune each time.

I'll be mounting the base at bumper level off of the left side of my
pickup (offset from hitch mount), and can probably deal with 9 or 10
feet total height from the mount.

I have an Atas-120 currently mounted at the back edge of the roof, with
it's base at roof level, but am not impressed with it's performance and
am looking for something with higher efficiency. The convenience of
automatic tuning with my FT-857 is less of a convenience than I thought
it'd be, especially considering it doesn't seem to have good efficiency.

Any Ideas?

Thanks

It looks like I could place a loop around the eaves of my house and it would, in theory, be resonant around the 40m band. I'm planning on either feeding it with ladder line or use a 4:1 balun with a very short run into the house.

How can I make the antenna also resonant on 75m? I am planning on using it for 75m-10m.

Randy ka4nma

>75m-10m.

Hi Randy,

It would help to have dimensions. Presumably the perimeter is 40
meters, or thereabouts. As you stand very little chance of one
antenna being resonant on all bands, you may as well anticipate tuning
on the majority of them.

As such, it behooves you to avoid dimensions that are problematic
(presenting a hi-Z impedance). The first likely opportunity will be
with 20M. If you carefully choose your transmission line length to
handle this, you may find you've forced the problem into another band.

As such, some flexibility is in order. One such forethought would be
to have a way to open the loop at the point opposite to the feed (or
perhaps kicks in a tuning cap). This says nothing of the matching
problem that has not already been said (be prepared), but it may be a
simple variation that yields new solutions.

Hello,

I need to built a simple, cheap antenna system for a 2.GHz audio-video link. At the moment I'm just using thick wire as the antennas on the transmitter and receiver. This system works surprisingly well... except for one little glitch:

While moving the transmitter, I find there are small, highly localised patches of space where the radio link fails completely. These "dead" patches of space are only a few square centimetres in size.

I'm not a radio engineer so I'm not too sure what's going on. If I was forced to make an educated guess then I'd say the problem was caused by interference caused by reflected, out-of-phase signals. For example, it's conceivable that the receiver could be picking up two 'copies' of the transmission from the TX - one 'copy' is the direct signal, the other 'copy' is a signal that has bounced off some surface - these two 'copies' would cancel eachother out when they're 180 degrees out of phase.

So... this brings me to the question I posed in the subject line: why do WiFi basestations use two antennas? For example, my 3Com basestation has two little whip antennas sticking out the back. Are these two antennas used to combat the problem that I am experiencing? If so, how can I implement two antennas on my system?

If not, how else can I combat the problem I am experiencing?

A little more info about my system:
The system is part of a wearable camera with recorder. The camera, transmitter, microphone and a battery are all worn in a hat. The receiver, recorder and battery are worn in a bag. The system doesn't have to transmit very far (only a few meters) but I do need the signal to be stable.

It's a technique called 'space diversity' that is also used in many radio
systems such as radio microphones and cellular radio. Two separate
receive aerials are used, on the principle that they are unlikely to both
be in a null at the same instant. There are various techniques to
implement this which range from simply coupling the two antennas together
to having entirely separate receivers and just selecting the best signal.
In your case it will complicate things considerably I'm afraid.

-Arthur

Hi Randy,
The best way would be to open the loop on the opposite side from the
feedpoint when you want to work 80m. I would use a relay of some sort
that could be activated from the shack. Also would go with open wire if
possible.

Arthur wrote:
"---to implement this (space diversity) which range from simply coupling the two antennas together to having entirely separate receivers and just selscting the best signal."

The latter works. The former doesn`t.

Coupling two antennas together produces a directional array, not space diversity. The only way to produce space diversity is to selsct a signal from a group while rejecting the others. With multiple signals, there is always some combination that can produce complete cancellation.

Best regards, Richard Harrison, KB5WZI

The best 75m mobile antennas at the previous shootouts have been
either bugcatchers with top hats or screwdrivers with top hats.
Such antennas are about 12dB better than a 75m hamstick.

If it is one WL on 40m, it will be 1/2WL on 75m. Install an insulator at the
half-way point. Leave it open for 75m. Jumper across it for the higher bands.

True, at a particular frequency. But, inductive impedance increases with frequency. Capacitive impedance decreases with frequency.

The parallel resonant circuit may have extreme impedance, but at higher frequencies it may have a very low impedance, especially if the resonant circuit is a high-C circuit.

The size of the house is about 25 feet by 40 feet, not including the 2 peaks of the roof line. This gives a resonant frequency of about 7.7 mhz. The addition of the two peaks, hopefully will bring it down to the 40m range. I was thinking of adding a 1/4 wave 75m stub to the antenna.

I am more interested in effeciency and performance than being resonant (yeah, I know that resonant antennas are more efficient...), but I need a good, multiband antenna.

Randy

Hi Randy,

Actually, we get many "designs" that are fully resonant and wholly inefficient. I won't offer the exhaustive list. Suffice it to say your antenna will be big enough to reduce some inefficiency inherent in Ohmic losses in the structure, but for the lower bands you will be in the deadly embrace of nearby lossy ground. You may note this in the resonance having a broader curve (lower Q) than theory would provide for the same structure in free space.

Rick
I use a Tarheel screwdriver because the base is 4 feet long.
I operate the antenna at resonance and match the impedance to the
transmission line with a transformer.
This approach, along with a top hat for 80, produces the best field strength
I have been able to measure.
A Hustler base with a bug catcher works well also. For the higher bands the
Hustler resonators are fine.
Continuously loaded antennas like the hamstick work less well but are
broader in bandwidth.
A whip and tuner is the worst.
Cecil is quite correct about the shootouts.

Unfortunately, morbid obesity is also common. Not so in the old days.

Having dropped some pounds I can attest to the problem personally(although not quite at that extreme).

Of course, having donuts and chili as the main draws on the event menu doesn't help.... not many healthy alternatives.

What we need is a merger of ham radio and orienteering...

being tucked under the eves of a house will be neither good nor efficient, it will be too close to wiring, piping, metal gutters, drip edge, and who knows what else inside the walls. it will also pick up noise from everything in the house on receive, and likely get into any poorly shielded electronic device in the house.

that being said, put up whatever is physically easy to do. leave off the balun and run to a tuner in the shack and be done with it. it will work everywhere your tuner will handle it. if the tuner can't handle a particular band try opening it opposite the feed point or change the length of the feedline to give the tuner a different impedance to match.

Richard,

On 75m and 40m, I am interested in NVIS. For 20m and above, DX.

The soil is sand - high desert sand. I am also on a hile. On the side with the feedpoint, we have a small walking space about 20ft from the antenna. After the walk space, a drop off occurrs of about 40 feet to the next street. The next side will have one of the eaves and be 15' high then go up the eaves to about 25' or 30' from the ground, then back down to 15'. The front will be about 15 feet high. The next side will be like the first one with eaves, and then back to the backside of the house. I am guessing on the heights.

I am wondering about the 450 ohm feedline. It would pass near (less than a foot) my pc on the way to the rig and tuner. Would it cause RFI?

I also have an offer of 4 5ft mast. Would it help to use the mast to push the antenna up a litte more?

On the frount of the house, I am planning on running the wire under a pvc rain gutter. We have the power feedline coming in from the pole to the service at the front.

Randy

>It looks like I could place a loop around the eaves of my house and it would,
>in theory, be resonant around the 40m band.

I have such an antenna. It varies in height from 8' to 20' (at the roof peaks).
It is in an 'L' pattern (as is the house exterior). It is slightly more than
200' long and most is #22 wire (in the hidden areas), with a short run of #30
across the front porch area. My MFJ analyzer says it's resonant below the 80M
band.

>I'm planning on either feeding it with ladder line with a very short run into the house.

I feed it with about a 20' length of ladder line.

>or use a 4:1 balun

I originally tried feeding it direct using an unbalanced manual tuner but this
required manual tuning on all bands (a pain), and produced some RF in the shack.
(Not much, but enough to get into my cordless earphones and be annoying.) Using
a 4:1 balun not only solved the RF problem, but also made my TS870's auto tuner
happy on all bands except 80M.

>How can I make the antenna also resonant on 75m?

I don't think you need to. Just hook up a tuner and play around. (BTW I got the
same signal reports with and without using the 4:1 balun, so if it doesn't solve
any problems for you as it did me, leave it out...)

>I am planning on using it for 75m-10m.

I've made contacts on 80M thru 17M (so far) using this antenna, and get mostly
average reports, nothing spectacular, but nothing bad either...and I am on the
air. I have 2 Hamstick dipoles in the garage attic (about 9' up) for comparison.
The loop always beats the 40M Hamstick, usually by 2 S-units or more. The 20M
Hamstick beats the loop most of the time, but usually not by much. Apparently
the loop becomes less effective the higher it goes.

Perhaps with some experimentation I could improve things. However I am satisfied
and will leave it alone. I want 'double stealth', that is not only can neighbors
not see the antenna, but also that they don't even know that I'm a ham. I think
that will save me a lot of grief with this low close antenna...don't you... ;)

Hi Randy,

All things considered above tends in your favor - a sort of solution
that when life offers lemons, make lemonade.

>I am wondering about the 450 ohm feedline. It would pass near (less than a
>foot) my pc on the way to the rig and tuner. Would it cause RFI?

Depends mostly on balance and thus Common Mode issues. Unbalance
arrives by virtue of lack of symmetry somewhere in the system. The
close proximity of the antenna to various structures tends to increase
the likelihood. Anticipate RFI such that you can add a BalUn (if it
makes sense) and cable. The only virtue of 450 Ohm line is in low
loss, but you won't have a long enough run for this to really matter
much.

>I also have an offer of 4 5ft mast. Would it help to use the mast to push the
>antenna up a litte more?

A 45 foot "mast?" Are you prepared for all the guying? If so, you
could as easily build a top loaded vertical. Don't reduce your
options and walk away from the house-wrapped loop though.

>On the frount of the house, I am planning on running the wire under a pvc rain
>gutter. We have the power feedline coming in from the pole to the service at
>the front.

Well, this speaks to issues of symmetry and balance. This could be
opportunity in disguise (more lemonade) where you put the open into
the loop.

Really, all the compromises you could make (aside from laying it on the ground) will have negligible effect on performance. Putting it up higher follows the maxim "more wire - higher" to advantage.

>the longest oxymoron in radio speak.

Why?
Among HF mobile antennas there those that have low, medium and high effciency.
It is acategory that is limited by some 13' in height and size of the car. One
that produces most signal would be even highest efficiency than the rest of
them. No?

The low efficiency antenna is 1% efficient. The high
efficiency antenna is 2%. That's double the efficiency.
I wouldn't judge efficiency on the basis of a shootout unless
the results were measured in the far field.

They were measured in the far field, a good 1/4 mile away.

## 221. Yagi Balun designs

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-08 04:13:22 UTC
From: vk4akp@yahoo.com.au
Message-ID: <a1284bc8.0410072013.4eb95f6f@posting.google.com>
Source record: 88716

Hi I have a friend writing a neat yagi design program. I'm trying to find info so he can include a couple of different balun design calculators.

One is the design for having the coax internal to the driven element, much like commercial designs.

The other is where flat material is used and the driven points of teh folded dipole meat in a `Z' style patern.

Both these designs offer good matching and ease of construction compared witht eh triditional external coax designs that also require more weatherproofing etc.

Can anyone help with info or links or formuila's on how to work out these types of baluns?

(Please email me direct as I'm not a regular visitor of this forumn).

Thanks,
Ken. VK4AKP.

I agree also that the second antenna is for diversity but none of the
manufactures can answer why it is needed if spread spectrum is suppose to be
so innately fade resistant, even though the spread spectrum Wifi is using
now with CCK isn't really truly random anymore.

With very short direct and reflected paths typical in indoor
installations, you are not going to have multiple nulls within the
spread frequency range. In order for a spread spectrum system to work
properly in a multipath environment, there should be several multipath
nulls within the spread range. If there is only one wide dip covering
your spread range, it can take out most of your signal.

If the spread range is from say 2400 to 2430 MHz, the corresponding
wavelengths would be 125 - 123.5 mm so the spread in wavelengths is
1.5 mm so you would need at least a path difference 40 wavelengths or
5 m to get a phase difference of 180 degrees that would cancel the
signal at one end of the spread range but add up in the other end.

With a larger frequency spread or larger path distance between the
direct and reflected signal, the phase difference would be several
times 360 degrees and there would be multiple nulls (at 180, 540 etc
degrees) and multiple peaks, within the spread range, which the spread
spectrum modulation could easily tolerate.

The Hy-Gain 18HT Hy-Tower is best all around non compromise vertical.
Hy-Gain has resumed mfg. in MS and several have phased 4 of them via
Comtek's ACB-80.
(http://www.comteksystems.com) Covers 10-15-20-40-80 meters.
New list is $749. with slightly less from dealers. A 160 kit is
optional.
MFJ-1792 is a 40 & 80 vertical; full 1/4w on 40 with a Teflon loading
coil and spokes at the top for 80. About $140. So one extreme to the
other on price if bought new.
Both need radials, as do all 1/4w series fed verticals, for best low
angle takeoff performance.

i suggest using WD-40 and a scotchbright pad
just spray the element down with WD-40 then wipe with Scotchbright pad
till clean then wipe off with paper tower
works well and low on the elbow grease scale as well

You might try Noxon liquid (available in grocery stores) and a rag. Probably easier to use than any kind of pad. I would also dismantle the driven element, and clean off with steel wool any portion that gets clamped/bolted together.

Advice from several gurus as garnered from the news groups over time.

For cleaning aluminum tubing, an antenna guru recommends the use of #0 steel wool, along with dishwashing detergent. Another guru prefers Scotch Bright. First wet the aluminum tubing with water and wet the steel wool. Add a small amount of dishwashing detergent to the steel wool and then scrub the aluminum. Rinse out the steel wool periodically with water. Then add more dishwashing detergent to the steel wool and clean again. Rinse off the aluminum tubing periodically. After cleaning a piece of aluminum tubing, rinse it thoroughly with clean water and then dry it off with a clean rag.

When assembling an antenna, apply a very thin film of Penetrox-A anti-oxidant to all of the aluminum-to-aluminum connections. Unless you totally disassemble and clean the traps, never attempt to clean the outer aluminum shells of antenna traps as water and steel wool fragments can enter the traps causing shorts and excessive trap moisture content. When assembling any aluminum antenna, put a thin layer of based-based anti-seize compound on all aluminum to aluminum joints.

These are Penetrox-A from the Burndy Corporation or another is Noalox. Never varnish any antenna - the varnish penetrates into the joints and causes continuity problems. Painting antennas for stealth can be done. Disassemble the antenna, apply paint, then scrape away any paint where the aluminum makes an electrical connection. When restoring an old antenna, consider replacing all the hardware (nuts & bolts) with stainless steel.

I cleaned up an old beam I had laying in the junk heap out back of my barn. The thing had been there a good 10 years. I had just clean my air conditioner condenser coils and had some cleaner left over so I gave it a spray and hosed it off about ten minutes later. This got most of the gunk off. A little work with a scotch brite pad made it pretty.

I've read that using steel wool will result in tiny pieces of the steel
being left embedded in the aluminum, resulting in long term pitting and
corrosion. Is that an old wives' tale, then?

Hi Randy,

You mean one at each corner or the house for 5 foot elevation? Or do
you mean all four combined for a one time gain of 20 foot elevation?

I have an Army field grade mast kit with 8 five foot heavy duty pipes
that does a good job (the kit also includes stakes, cording and plates
for 3 tiers of guys, and a 2.5 pound sledge). Works fine, but if I
wanted 20 feet, I would go buy two 10 footers. You have to be careful
these days about your pipe sources. Some in the CIA would claim they
could be used in Uranium Centrifuges and a cruise missile may be
targeting you soon.

If we fall back on the 4 spread among the corners - nah. Too much
work for wholly no observable gain.

Message-ID: <ck7bgb$f65$1@titan.btinternet.com>
Source record: 88638

NOW AVAILABLE ** New Program "TRAP3.exe"

This program calculates the performance of an antenna trap. It also assists with selection of trap capacitor value, coil length and diameter, and number of turns. For full design of a trapped dipole use in conjunction with program TRAPDIP.

An independent signal generator is built into the program. It generates a testing frequency which allows the traps's performance, input impedance versus frequency, to be 'measured'.

One small file, size = 43 kilobytes.

Have you ever wondered what your traps are really doing? Download program from website below in a few seconds and run immediately.

Hi Tam,

Actually, the ones that looked easiest to use were the 1210 case size. I ordered some from mouser yesterday. I hope they're big enough for me to see.

I was wondering about a post I read somewhere else a long time ago. Is there such a thing as a paste (that comes in a tube) that can be applied to the terminals of a surface mount device and then when it is stuck to the board, the paste hardens into something like hardened solder? So it is mounted to the board and soldered with this paste?

Save your $$. I was in the same spot you are and went for the Tarheel and the W4RT auto tuner box. $500 or so later, I A/B compared my old roof mounted ATAS 100 against my full size Tarheel on the bumper and the ATAS was so close on 20 and above, I could not tell the difference. On 40, the Tarheel was a slight favorite. Of course the ATAS does not run 80.

Theory: mounted up higher the lower efficiency ATAS overcomes its shortfall because it has lower ground losses than the bumper mounted larger antenna. Some modeling I did with G4FGQ's MIDLOAD seemed to confirm that would be the case.

Another way to consider it: Mobile operating is unique in that signals had better be pretty strong to begin with or you won't hear the station over the cab noise, QSB from moving past a truck and RFI from the cars around you. To say the full size screwdriver is two S units better on 40 means nothing because you couldn't understand an S2 signal on the full size either. If the signals are strong enough, an S9 on the full size is just as copiable at S7 on the ATAS and is enough to get the job done.

One-part conductive epoxy fits that description. It's commonly used to mount SMT parts on hybrid circuits. However, the ones I'm familiar with require curing at an elevated temperature (e.g., 150C for an hour). I believe there are also some UV curing conductive epoxies. Conductive epoxy can be used for mounting parts on a PCB, too, but I don't think it's commonly done because it's considerably more expensive than solder. There might be two-part conductive epoxies that cure at room temperature, but I've never used one and am not sure they exist. The one-part epoxies I've used aren't conductive until they're cured -- the tiny conductive (gold or silver) particles in the paste don't contact each other until the curing process causes the epoxy to shrink and pull them together.

Then there's solder paste, nearly universally used for mounting parts on PCBs. This also fits your description and can by applied by hand with a syringe, then melted by a number of means -- hot air, IR, soldering iron. It's actually a slurry of flux and tiny spheres of solder. It's not really sticky, but sort of gummy, so some other means (like superglue) has to be used if the parts need to be kept in place when the board is inverted or severely disturbed before the paste is melted.

## 248. solid or stranded copper best ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-09 03:11:16 UTC
From: carkenord@juno.com
Message-ID: <4346b55e.0410081911.70664e36@posting.google.com>
Source record: 88643

My old delta loop on 20M SSB finally quit. Actually, it was destroyed in a hailstorm. It was made of 18 gauge solid Copperweld, and stayed up in the Denver smog for many years.

This equilateral antenna was mounted vertically, with apex up, fed in middle of base.

It was a real good antenna, and I'm going to put up a replacement, with same basic parameters.

In terms of strength, longevity, fatigue resistance, and resistance to stretching which would be better, 12 to 16 gauge solid copper, or 12-16 gauge stranded copper?

Insulated or non-insulated?

If I use insulated 12-16 gauge copper, how much should I shorten the overall length, expressed as a percentage, as compared to the bare 18 gauge Copperweld I had up before the storm? I will want this antenna cut for same freq (14.225 Mhz) as the previous one.

Thank you..... Lee Carkenord KA0FPJ

No ! It definitely cleans and shines the anternna so objective is achieved.
Regarding possible destructive action , can you point to a study
that shows measurable losses with respect to exposure time ?
I am assuming that you are refering to cases where a sizeable portion of the
aluminum surface is removed and replaced by steel which somehow
prevent skin depth from attaining its original depth. ( not what the normal
operator had in mind)
But if you are refering to corrosion of the embedded steel particles
'tiny bits' that would be a nye impossible loss to measure and thus would
take it's place as "an old wives tale"
( Unless you have a study that proves otherwise
such as a .01" lump of steel embedded in a 1" diameter tube
provides a measureable loss )

I have seen commercial wire antennas where the insulated wire is tied
to the center insulator with a clinch knot having three turns and then
the end of the wire (protruding from the knot) is stripped and
connected to the feedline.

Does forcing the RF current though a knot at the feedpoint have a
significant affect on propagation?

I would say yes - it would have an effect - but not so much on propogation
as efficiency - I think the knot would act as a loading coil.
I would think it best to strip the insulation so the whole knot is bare
copper.

I used 14 ga THHN (stranded, insulated) with black insulation. It worked.
I would think 14 ga copperweld (copper-clad steel) would be ideal, but THHN
was easily available at the local builder supply - and cheaper.
Maybe the small guage wire you used contributed to its demise - 14 ga
version of what you were using would be my first pick.
Stranded wire is more flexible than solid, but that attribute may be moot
once the antenna is in place.

Hi Ken,

YES, at wavelengths of 1cM that 1cM knot puts the twists to RF.

NO, at wavelengths of 160M that 1cM knot is invisible.

MAYBE, between those two extremes your answer varies in proportion.

It would not look good for a preacher to be hit by a cruise missile. :-) Hmmm, maybe the flaming arrows of spam are from the cia???

Ok, I will scrap the 4 pipes around the house for loop's extra elevation, and use them for elevation for a 2m J-pole.

With the power company feedline coming in at the front (away from feed point. would a "U" shape (that is a loop with a gap around the power line) work. I think that I just realized the answer. It would or could cause an unbalanced situation which could lead to all sorts of problems like RFI, unable to tune, etc....

I am also thinking of running the loop along the backside of the house and then instead of continuing to run along the side of the house, run the wire to an old unused billboard (about 20 or 30 feet high) and then from the billboard back along the front of the house, and then instead of along the side, run it to a tree (the only one on my property) and then back along the side of the house. The feedpoint would be on the backside about 1/4 or 1/3 from the tree side.

An idea, if, I use the 2 of the pipes as additional supports placed at the top of the side eaves , I could run a wire from the tree over the roof to the billboard, sort of an inverted V or a droopy end dipole with a slight bend on one side. And if the pipes are placed just right, then I would not be running a wire under a power feed line, like the loop on the eaves. It would be random length, and feed about 1/3 or so from the tree end, unless I got more ladderline. Total length about 60 or 80 feet at about 20 or 30 foot sloping down to about 10 or 15 feet at the tree. Let's see, a random length dipole in the clear (by a few feet), should out perform a loop under the eaves? Easier matching, antenna in the clear, less RFI, better for NVIS and DX. Maybe a better antenna?

Can an OCF dipole be feed with ladderline?
What is the best way to run ladder line over asphalt shingles?

Randy

Hi Randy,

All of this is actually a long shot - very unlikely. If it DID happen
you have a scapegoat, but RF is not that delicate a flower rent by the
hurricane of speculation. In other words, try it to see if you have
a problem. You will spend far less trying compared to the time
worrying about the possibility.

>
>I am also thinking of running the loop along the backside of the house and

>better antenna?

Whoops! Backsliding to that familiar nemesis of "a solution in search
of a problem." You are trying too hard to put those tubes to work -
use the abandoned sign. Dare I say it is a "sign?" The metaphor is
certainly not lost on you is it? ;-)

>Can an OCF dipole be feed with ladderline?

It typically is and it typically is fed with coax too - howabout that for political answer - sorry, watching too many debates. We taped the soap opera when we went out to listen to Mort Sahl here in town. Mort is getting on in age (wish I could have caught his act at the Hungry I in Frisco) but he is as sharp as a tack still... and then we got back for the punch and judy show as a retread. I wanted to throw the remote at those two monkeys. Politics is a sure argument against Darwin (evolution caught in a time warp).

OCF guarantees Common Mode for any feed. It is up to you to force a new balance.

>What is the best way to run ladder line over asphalt shingles?

The asphalt isn't a problem, it's the water and crud that comes with the rain that bridges the wire. Use coax for short runs because you would need standoffs (like they used to use for TV twin line back in the old days) but you are back to loss due to water and crud that comes with the rain that bridges the wire (get the idea?).

Or just simply ignore the loss of the water and crud that bridges the wire (or ignore the loss of coax) and get on with the fact that no one can tell the difference with WHAT you use (come what may, rain OR shine).

One of the supreme ironies is that most folks achieve their greatest improvements with very little work, and then they have to struggle to double that performance gain - and then they have to quadruple that heroic effort to double it again. Ever hear about the problems of Sisyphus?

Of course. The receiving s/n ratio *should* be about the same on
anything you use, being you have way more signal than you need with
even the worst antenna. Or at least on the lower bands. But that 2 s
units can mean a lot to whoever you are talking to, if the noise
levels are high. I wouldn't say it means nothing. Thats like switching
on an amplifier. MK

Source record: 88656

Hello,

i would like to make my own antenna for CB radio, mostly because i am interessted in the technics involved, not strictly because of saving some money.

I was googling a while but unfortunately the information i gathered was rather unsatisfactory. Quite some theory but lack of practical descriptions.

Are there good links to pages how to make it's own antenna?

I am interessted in an antenna which gives me a good trade of between gain, ease of operation and ease of manufacturing.

I think now that either a "long wire antenna" or a dipole would be the best for my purpose. I would place both vertically on a fishing rod. A horizontal adjustment would yield better results in DX but not so good results for near communication, right?

But i wonder how i can make a balun on my own. I guess i need a 1:1 balun for the dipole (i use rg58 to the radio) or a 1:4? balun for the long wire.

Would the two antenna types be a good choice?

Any help would be appreciated.

Greetings,
Johann

you know what... it doesn't matter. pick one, put up some wire, and put the
rf to it. situations like this are WAY too complicated for even the most
dedicated computer modeler. the best recommendation anyone can make in
cases like this is "Plug it in and try it". if it works, great, if it
doesn't work or causes problems then change something and try again.

it has absolutely NO effect on propagation. it might have a tiny effect on the feedpoint impedance at uhf, but then again you most likely won't use an antenna like that at those frequencies. i have always thought that buying wire antennas was the worst possible thing to do, they are expensive relative to the material that goes into them, they are no better than something you can build from stuff found around the house, and they are full of excuses... they are too long for your property: if you built from scratch you would cut it off and use it anyway, if you buy it you don't want to cut it. it doesn't present a good swr: if you build it you trim and adjust until it works or just put a tuner on it and forget it, if you bought it then the problem must be the balun or a trap so send in to get a replacement instead of getting on the air. etc, etc, etc.

Got a motherboard the other day that has a Marvell Yukon gigabit chip on it.
Comes with "virtual cable tester" (VCT) software. Reading the white paper
on the Marvell site it turns out that the VCT uses a TDR built into the
gigabit chip.

Board with those chips are available for 30 bucks.

I am in general agreement. I asked because I am making my own QRP 40M double zepp and was trying to decide how to attach the 26 ga stranded, insulated copper clad steel wire to the center conductor. I like to leave the insulation on because the knot does not weaken the wire as much as putting a knot in bare wire (smaller radii). I was considering stripping a section of the wire just beyond the knot and soldering the feed lines there, but figured it just wasn't worth the trouble.

If stranded and bare, moisture can get between the strands and shorten
the life. There might also be some added noise.
>
>Insulated or non-insulated?

For stranded wire in your climate, you probably want it insulated.
>

My Wirebook IV says shorten insulated antenna wire by 1 to 4 percent.

I'm having pretty good luck on an 80 meter dipole with the Wireman's
#18 stranded, "silky" insulated CCS.

On Fri, 08 Oct 2004 19:15:22 -0500, Butch <lynyrd@cableone.net> wrote:
>Bullet proof vest showing.

Hi Butch,

The New York Times reported the Salon report of this, and did some follow up by calling the White House.

First they said the picture was doctored.

Hmmmm, no, it shows in the video stream quite plainly.

Could it be his bullet proof vest? They said, no, he wasn't wearing one.

Then they said it was a wrinkle - an oblong rectangular wrinkle. (Presumably shrub sleeps in his suit or worried it into knots back stage).

Anyway, I missed the live feed last night - tape spared me the misery of having to see the entire snooze-fest. We went to hear Mort Sahl who stunned the audience by telling us he had done a Republican benefit.

Mort was invited by his West Point classmate, General Haig, to Haig's place on a barrier island in Florida for a meeting of a small circle of 33 friends. They all stood around and chit-chatted and someone asked the prez a question about his days boozing and smoking crack. The prez turned to Rove, they conferred and he turned back and said he was a different man from then. Some on mentioned about his born again faith and asked about a quote of his about going to heaven "wouldn't Jesus, under your definition have a hard time getting into heaven?" The prez again turns to Rove, they confer, and he turns back to offer "they don't make Jews like they used to."

Then it was Mort's turn one-on-one. The prez took his hand and asked "Are you prepared to make a sacrifice to fight terrorism?" Mort responded quickly "The spirit is willing, but the flesh is weak after having fought the communists."

Well, the upshot of this meeting is those 33 took out their pens and wrote checks to the sum of $1,370,000.00. Presumably it helped buy a better RF link system and covered the salary of a debate coach (they should get a refund).

Lee,
I think it's more a matter of preference than actual
(practical) differences between stranded and solid wire.
There is the possibility of interaction between the strands
of stranded wire (corrosion, smog, 'stuff'), no idea if it
would be objectionable in your area. One 'alternative' if
you decide on stranded wire is to use insulated wire and
seal it where you have to make connections. Ought'a make it
last longer before any of the 'interaction' between strands
begins.
You already have a fairly good idea of how long Copperweld
will last. Other types of wire will probably last about as
long, sort of.
The diameter of the conductor at HF is going to make very
little (if any) practical difference in length. You will still
have to do the normal 'checking and chopping' for resonance and
that will take care of any differences because of diameter. It's
frequency dependent, the higher the frequency, the more difference
it will make (but we're talking huge differences in frequency, not
Khz or Mhz differences).
The 'best' kind of wire to use is whatever you happen to have
the most of...

You'll find a simple dipole may be your best choice for starting out.
Most important of all is to get the antenna up high and use vertical
orientation.
If I recall, each leg of the dipole should be around 102 inches.

I certainly will not! I'm also a UK amateur/ham who attends rallies so
the slur is equally applicable to me as well. The remark is a
generalisation, of course and doesn't apply to every single ham in the
country. Just a significant proportion. But I dare say the same could
be said for train-spotters, real-ale enthusiasts and stamp collectors.

Thanks Roy,

It sounds like the solder paste is what I heard about. Sounds easier than
trying to solder such small parts with an iron. I will see if mouser carries
it and give it a try.

Get yourself a empty can of coffee. Place a light bulb in it. Hook the
coax to it. Remember the shield goes to the negative of the bulb.

Seal the can with lead solder.
Bury 15 feet underground.

Enjoy.

Hi Butch,

I ran into Mort and like satire courtesy of innumerable venues like Jack Paar (I always tuned in for Oscar Levant, "Memoirs of an Amnesiac"), Ernie Kovacs, Steve Allen, TW3 (That Was The Week That Was), Lenny Bruce (Who Was that Masked Man?) and found that talent that came out of the Hungry i (Shelley Berman, Jonathan Winters, Dick Gregory, Bob Newhart, Bill Cosby) was always top-notch.

Following Rodney Dangerfield's death last week, a New York Times writer noted that very few of the original Borscht Belt comics were alive. He went down the list and decided to call Don Rickles. When they were talking he mentioned Don was the "last comic standing." Rickles in his inimitable form said "you mean like a Jew at the Alamo?"

Mort had some comments about today's comics on the cable - much too vulgar. The vice-prez conforms to this without shame and certainly no humor (talk about old). As far as these comics' political savvy, he said they were all too conscious of keeping their jobs to "go there." This is from a man who laughed at 10 presidents (for good reason).

As for the age factor, the audience was gray to say the least. However there were a smattering of younger members in the audience and when he opened the mike to questions, they lit up like firecrackers to his observations.

Last week we went to listen to Daniel Ellsberg and company and following the questions, we walked out and I had to mutter "What a bunch of Whackos!" My XYL stuck her elbow in my ribs to keep my voice down (but smiled at the observation nonetheless). It was like being at a meeting of the young republ -eh- communists (hard to tell the difference these days).

It seems, as always, that comedy is revolutionary and politics is laughable.

## 287. Incorporating a Terk TV-5 as part of a beam?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-10 04:59:41 UTC
From: Richard Lane <rqlhgl@ieee.org>
Message-ID: <4168c2ef@sys13.hou.wt.net>
Source record: 88582

I live 50m from TV transmitters, want to enhance ch9 (187mHz) without using a roof antenna and have a Terk TV-5 amplified set top antenna. Is it possible to place directors ahead of its dipole and a reflector behind to increase the forward gain and null some of the multipaths?
Dick

Yes, that's what you'll be telling you lawer when you've been done for
kiddie porn. (joke)

But, seriously, that sort of evolutionary psychology is fatally flawed. The
most glaring problem with it is that we're social animals - what makes us
humans different from all other animals is our ability to share thoughts.
What makes humans such a powerful (or lethal, depending on your perspective)
species is that we no longer have to wait millenia to evolve new faculties -
we can evolve *culturally*, which is orders of magnitude faster than
biological evolution.

So, what I'm getting at is that there are loads of reasons for associating
with other people other than to get your end away. What we're doing right
now is an example - we all feel compelled to share our thoughts on these
news groups without any desire to have sex.

Jack.

Reg is right, but it's an oversimplification. The contact can be
indirect for the purposes of self-propagation. You might not want to
shag the person you're shaking hands with, but you presumably want to
make a good impression on them. Maybe it's a job interview; maybe
you're making a new friend; whatever. The motivation (usually
subconscious) behind the gesture is to better your chances of
replicating yourself; increasing status/wealth-generation/social
standing, whatever, are means to a successful biological end.

## 297. EH-antenna: sensation or fraude?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-10 12:37:59 UTC
From: bozidar.pasaric@ri.htnet.hr

EH-antenna: sensation or fraude?

I have been reading about the EH-antenna on many web sites and in magazines, but they were only "kitchen recipies" of how to build it - without any theoretical explanation. Practical result reports were mostly contradictory - from being equal to a full size dipole, to statements that the antenna does not radiate at all, but the coaxial lead does.

The other day I ran across the EH-antenna home web site (http://EH-antenna.com) where finally I could find the expected theory - which left me embarassed. It comes out that the EH antenna uses an until now unknown kind of magnetic field - completely different from the usual H-field. "The EH-antenna is a revolutionary concept because it does not fit the classical theory" - I can read on that Web-site. In a classical dipole the phase-shift between the E and the H field is 90 degrees. In the EH-antenna it is 0 (zero) degrees! A certain Russian phisicist Vladmir Korobeynikov reworked the famous Maxwell's four equations and they are now called "enhanced ones". Possibly he will be candidated for the Nobel prize in physics (!?). Since magnetic force-lines are closed and cannot be cut apart, underwater EH-antennas allegedly work equally well - a bonanza for submarines! It also seems that those force-lines spread across the whole Universe in zero time - which challenges the Einstein's theory of the limited speed of light to 300 000 km/sec. If all this is only partly true, this will be the greatest discovery after Heinrich Herz discovered radio waves 130 years ago.

They also say that the best communication is made between the two EH-antennas. Has anybody tried that already? I do not wish to be a primitive Earthian who does not accept progress in science; however, life has taught me to be cautious. I would like to read an official report about the EH-antenna phenomenon from a competent scientific institution, a University, a research laboratory, or similar. Any comments?

Message-ID: <6bCdnVeZ45P4xPTcRVn-tg@comcast.com>
Source record: 88595

Hi John and others,

Interesting topic.. I also agree with the j-pole. Not to bend any
eyebrows.
(I also have 300ohm 2M j-pole designs web-posted )

The only comment is the use of 300ohm twinlead for antenna construction.
300ohm twinlead comes in several different variations and the velocity
factors are all over the place. So, results vary!! I've answered my fair
share of e-mails in the past 5 years, trying to explain this problem to
other new Hams. This can really discourage someone that tries to build a
first time antenna with the wrong type wire.

Stuff to look for:

Don't use the "thick stuff": also called the "Heavy Duty" with a heavy thick
brown plactic covering. It is very difficult to cut and almost impossible
to work with.

Do not use the "foam type": with foam covering the wire, between the wire
and the outside black plastic casing.

Look for the "thin stuff": and the flatter the better.

Another thought is to move to a different construction material with a
little more consistency: 450ohm ladderline, Solid copper type.
Ref: http://home.comcast.net/~buck0/ll_coolj.html

Hope this helps others!

## 304. Repairing a tri-band Co-linear 50/144/430 MHz

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-10 17:17:22 UTC
From: Brian Reay <brian.reay@bigfoot.com>
Message-ID: <2st93uF1nod3mU1@uni-berlin.de>
Source record: 88598

My triband co-linear has 'died'. It is a clone of the Comet GP15- the 3dBi, 6dBi, 8dBi beast about 8ft long.

I've found the fault- the capacitor that connects the inner of the coax to a tap on the matching coil. It has failed short so I can't measure it and it is too cooked to read the value.

Of course, I can have a play with a variable, checking with the antenna analyser or even SWR meter, but that will take more time than I can spare at the moment.

Anyone repaired one of these before and noted down the values of the C's in there?

102 inches, or 2.59 m for a metric man like me. That's right. But i bother how i can go from balanced to unbalanced. I use rg58 wire and i do not want to radio interfere my neighbours nor let my radio go up in smoke.

So i guess i need a balun. The impedance at the connector from antenna to wire should already be more or less 50 ohms, but it's balanced.

What would make an easy though effective 1:1 balun?

Gidday Johann

Simple balun you can use in this case is a "choke" balun. Just wind about 5 turns of the coax in a 100-150mm circle near the antenna feedpoint and tape it up. This will almost eliminate all of the line radiation.

Another way is to make a folded dipole. This has a nominal 300 ohms input impedence and feeding this with a 4:1 coaxial balun (200 ohms) is only a slight mismatch. (1.5:1 VSWR) I have also heard (but never checked/proven) that a folded dipole antenna couples to "space" better than a simple dipole. (ie is more efficient)

If you cant find an internet refernce to the above then pls ask for more info.

Cheers Bob VK2YQA

"A horizontal adjustment would yield better results in DX but not so good results for near communication, right?"

To reach beyond line-of-sight but not very distant locations, usually requires a reflection from the ionosphere nearly directtly overhead.

Vertical antennas tend to have a null directly overhead and tend to behave poorly for areas beyond line-of-sight that require an ionospheric reflection nearly overhead.

Low horizontal wires radiate substantial energy as antennas at high angles to the horizon, and thus they are suited to reaching areas beyond the horizon.

Best regards, Richard Harrison, KB5WZI

Hubris aside Roy, you still fail to address the
most salient: due to a programming
inconsistency - yours - your customer feels
he is left with no option but to come to this
NG in search of an answer to a dilemma.

Rather than apologizing for your programming
failure, you berate him instead.

If I were in your position (and I have been), I
would have made an apology, then offered
a free upgrade once the inconsistency was
resolved.

Is your ego so fragile that it is more important
than your customer's satisfaction?

Apparently so...

Indeed, it seems our views on business ethics
are as opposite as are our views on the need
to model a bi-directional coaxial phasing line,
as well as the induced energy that would be
present at the reverse input of such a line, in
a dual element (critically coupled) broadside
array.

> customers who continue to purchase upgrades, and the commercial
> customers who keep buying more and more copies.

Since yours is one of the few available
in-depth interfaces to the NEC(n) engine, this
is not surprising. What is surprising is your
cavalier attitude - I'd think a seasoned
professional like yourself would want to do
his very best.

Chuck, WA7RAI

Let me see if I understand.
A competitor of EZNEC feels a need to draw a red fish in front of one of the most successful and effective programs in existence. One wonders why.

Disparagement from a competitor is not appropriate. Especially since anyone may and can evaluate the suitability of EZNEC without charge.

Tout the advantages of your work on your site and let the market place work.

Hi Chuck,
I'm sure you're justifiably proud of
your own programming efforts, and there's no reason
not to brag if you want to, but writing posts like this
only serves to reinforce the notion among some readers that
you've succumbed to the temptation to act like a
sanctimonious ass.
The EZNEC manual is a good thing to read if you're going
to use EZNEC. There aren't many technical instruction
manuals in the world as well written. If you've ever had
to use a manual such as the old GE Fanuc machine tool controller
instruction manual which was machine translated from Japanese to
some language that only superficially resembles English, you'll
know what I mean.
As for being able to write a program that anyone can pick
up and use without the need for written instruction, that will

always remain an unrealizable fantasy, since the user's cognitive abilities are beyond the control of the program designer.
There's a name for people who write posts full of invidious little insults, and oblique little bitch-slaps, but I won't use it here. You can bet, however, that some of the people who read your post are going to use it, if only to themselves.
73,
Tom Donaly, KA6RUH

Some more comments about solder paste:

Solder paste has a shelf life. Unlike wire solder it will go bad after a
time on the self.
It cost more than regular solder too. Its also hard to use on components
like IC's with close spaced leads. In the commercial world the solder paste
is put on the board before the components are by a silk screen like process,
then the components are placed. The gummy solder paste is used to hold the
parts in place or if the board is to be inverted, to mount parts on both
sides they are glued in place. The problem for the "home" user is putting
the paste only on the pads of fine pitch parts other wise its no better than
wire solder. The method I use is based on a solder tip for my iron made by
Pace. They call it the "mini wave" tip. It has a oval shaped pit that you
fill with solder. It's used by tacking down the IC by hand using 1 or 2
easier to reach leads, then painting the part liberality with liquid flux.
It looks and is messy, then taking this "mini wave tip" with the pool of
solder and letting the ball of solder just touch the leads on the IC,
quickly wipe the solder pool down the length of the row of IC leads.
Capillary action and the flux pulls the solder onto the leads and does a
very good job of soldering. It takes a bit of practice and some solder wick
to remove the solder bridges that can happen until you get the hang of it
but it works and I've done IC's with up to 164 leads this way. For small
parts like resistors and SOTS and the like I use a very fine tip iron and
lots of liquid flux. Cleaning up the flux can be a problem but there are
flux removers that work. Another way is to use water soluble flux. This is a
very active flux and CAN NOT BE LEFT ON THE BOARD. It must be washed off
with water SOON after use. It's used with solder that also has the same type
of flux in. Soap and water and a small brush works well to clean the water
soluble flux off and leaves you with a very nice looking board. All most all
electronic components are not effected by soap and water as this is the
standard commercial process.

Mac,

Clearly, you do not understand!

Public disparagement of a customer with
a valid issue is not appropriate under any
circumstances.

And that's the issue I am raising here, as
well as opposing the cavalier attitude that
engenders such disparagement.

With all due respect, you erroneously
concluded I am a software vender, when
in fact, I am here simply as an interested
Ham who has a right to form an opinion -
good or bad.

|Mac,
|
|Clearly, you do not understand!
|
|Public disparagement of a customer with
|a valid issue is not appropriate under any
|circumstances.

Are you the "wronged" customer?

|
|And that's the issue I am raising here, as
|well as opposing the cavalier attitude that
|engenders such disparagement.
|
|With all due respect, you erroneously
|concluded I am a software vender, when
|in fact, I am here simply as an interested
|Ham who has a right to form an opinion -
|good or bad.

And a disingenuous one at that. You are an antenna vendor who has made
unsubstantiated claims about your product. When modeling has pointed
out those shortcomings, you claim that some new law of physics makes
it impossible to model your product and people selling those modeling
programs should be disparaged.

You have an agenda that overrides any legitimate criticism of Roy's
product or integrity. Shame on you.

Source record: 88530

I have search far and wide for this but have come up empty handed. I spent $25+ on a set of rabbit ears for my home set, and could not get good reception no matter what I did. A friend told me to push the end of an AC Adapter to the input of my co-ax cable, and set the plug where ever I need to get the best reception. It worked! Better than the rabbit ears. Has anyone ever heard of this before? Or, are there any other tips and tricks for getting the best reception?

No, although replacing rabbit ears with wire coat hangers (a dying breed!)
and bits of tin foil seem to have been common in times past.

>Or, are there
> any other tips and tricks for getting the best reception?

Sure... get a good outdoor antenna. If you don't like that idea and rabbit
ears aren't doing it for you, though... well... you can try fancier antennas
indoors as well, but if your current approach is working, by all means, keep
using it.

I would suggest _staying away_ from most of the spendier set top antennas
(including amplified ones) at, e.g., Radio Shack. Generally there's
negligible improvement over rabbit ears. (And it's not like you could tell
from looking at the package, either, since they don't include a graph of the
antenna's performance. :-( )

I used to live in Madison, Wisconsin where the downtown Radio Shack store
had a policy that prohibited the return of set top antennas. They said that
many college kids would move in, buy them, find they performed poorly, and
then return them! Sort of an odd policy... (Interestingly, the problem in
Madison was more often that you'd have severe ghosting than a poor signal,
and of course the only cheap fix for that is a directional antenna.)

## 342. Half sloper mounting

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-11 23:20:19 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <TyEad.6121$tn5.3117584@news4.srv.hcvlny.cv.net>
Source record: 88535

I intend to try a half sloper on my TX455 tower (with a tribander on top). I can connect the sloper to the top of the tower (about 55 feet up) or to the top of the middle section (about 38 feet up). Other things being equal, I would prefer the middle section (for maximum separation from an inverted V connected to the top section and at right angles to the sloper). The tower is grounded and will have a reasonable number of radials (when I can figure out how to best attach them).

I know that half slopers have been debated here and many other places and provide considerable confusion for most of us. I think I understand that the tower provides most of the radiation and the sloper wire is more a matching device than a radiation device. Should I expect significant improvement with a tower-top connection instead of a middle section connection? Would it make much difference? Are these things so unpredictable that experimentation is the only answer?

Wes,

Apparently, when you don't like a message
you attempt to malign the messenger...
where is the intellectual honesty in that?

In any case, I am not in business as of late,
as my wife is dying of cancer and needs all
my attention. And since I am not in business,
I can now express my views here without
being accused of commercialism.

Regarding my claims; you cannot provide
one substantiated instance where my
antennas did not perform as stated. Where
are the complaints? Where are the
dissatisfied users. One would think after TEN
years there would have been some indication
of a fraud if one did exist.

Or perhaps you simply imagine that all those
good folks who find my antenna design a
superior one, are merely deluded idiots, as
Brian Beasley once accused...

> When modeling has pointed out those shortcomings,
> you claim that some new law of physics makes
> it impossible to model your product and people selling those modeling
> programs should be disparaged.

Nonsense! I have made the assertion - and
I continue to do so - that minninec and NEC
based programs cannot model my design
simply from their inability to simulate a
virtual bi-directional coaxial phasing/delay line.
Furthermore, I hold the opinion that there are
no assumptions in those programs that would
recognize the induced energy that would be
present at the reverse input of such a line.

Do you have definitive proof to the contrary?

Let me suggest, that until you have something
of substance to offer in this regard, you should
refrain from making false accusations.

>
> You have an agenda that overrides any legitimate criticism of Roy's
> product or integrity. Shame on you.
>

<lol>... my only 'agenda' here is to point out
Roy's distain towards his customers who
cannot work through his inconsistencies...

Though, apparently, you have an agenda of sorts, otherwise you wouldn't be posting this garbage! Shame in you!

Chuck, WA7RAI

This all goes back to the solution of the differential equation for
the RC or RL system. e is a natural constant that has some very sweet
properties in many applications of mathematics, and simplifying
differential equations is one of them. Read through this tutorial and
see how the rate constant k in this tutorial is an example of a time
constant.

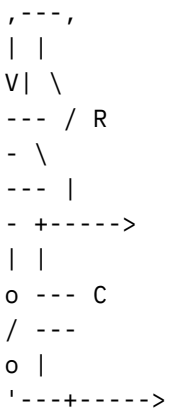
>the voltage "know" that it should be increasing exactly 63% during
>each time-constant period?
>
>And whence the number 63%?

I haven't had a chance to read other responses, but here's mine:

Take the case of an RC:



Assume C is discharged and V has just been applied by closing the switch...

The current through R is based on V, less the voltage on C (which counters V), so:

I(R) = ( V - V(C) ) / R

The above is a function of time, because V(C) is a function of time. So, what's V(C)? Well, that needs to be arrived at more slowly.

First, we know that this is true:

Q = C*V

Well, actually, that's an average statement. More exactly, it's:

dQ = C * dV

In other words, the instantaneous change in Coulombs is equal to the capacitance times the instantaneous change in voltage. Both sides can now be divided by an instant of time to give:

dQ / dt = C * dV / dt

Since dQ/dt is just current (I), for the above capacitor this becomes:

I(C) = C * dV(C) / dt

So how does this help? Well, we know that the current from R must accumulate on C. So, we know that:

I(C) = I(R) = ( V - V(C) ) / R

so, combining, we get:

C * dV(C) / dt = ( V - V(C) ) / R

Rearrangement of this gives:

dV(C) / dt + V(C) / (R*C) = V / ( R*C )

Which is the standard form for ordinary differential equations of this type.

The standard form with general terms looks like: dy/dx + P(x)*y = Q(x). In our case, though, y = V(C), x = t, P(x) = 1 / (R*C), and Q(x) = V / (R*C).

The solution to this includes multiplying by what is called "the integrating factor", which is:

u(x) = e^(integral (P(x)*dx)) = e^(integral (dt/RC)) = e^(t/(R*C))

(This is a VERY POWERFUL method to learn, by the way, and it is probably covered in the first few chapters of any ordinary differential equations book.) So, going back to look at the general form and multiplying both sides:

u(x)*dy/dx + u(x)*P(x)*y = u(x)*Q(x)

But the left hand side is just d(u(x)*y)/dx, so:

d(u(x)*y)/dx = u(x)*Q(x)

or,

d(u(x)*y) = u(x)*Q(x) * dx

In our case, this means:

d( e^(t/(R*C)) * V(C) ) = V / ( R*C ) * e^(t/(R*C)) * dt

Taking the integral of both sides, we are left with:

e^(t/(R*C)) * V(C) = integral [ V / ( R*C ) * e^(t/(R*C)) * dt ]
= V / ( R*C ) * integral [ e^(t/(R*C)) * dt ]

setting z = t/(R*C), we have dz = dt/(R*C) or dt = R*C*dz, thus:

e^(t/(R*C)) * V(C) = V / ( R*C ) * R*C * [e^(t/(R*C)) + k1]
= V * [e^(t/(R*C)) + k1]
= V * e^(t/(R*C)) + V * k1
V(C) = V + V * k1 / e^(t/(R*C))
= V + V * k1 * e^(-t/(R*C))
= V * [ 1 + k1*e^(-t/(R*C)) ]

From initial conditions, where V(C) = 0V at t=0, we know that k1=-1, so:

V(C) = V * [ 1 - e^(-t/(R*C)) ]

Time constants are usually taken to be:

e^(-t/k)

with (k) being the constant. In our V(C) case, this means that k=R*C. So
that's the basic constant and it's in units of seconds.

So, what's the voltage after one such constant of time? Well:

V(C) = V * [ 1 - e^(R*C/(R*C)) ] = V * [ 1 - 1/e ] = V * .63212

Ah! There's that 63% figure. Actually, more like 63.212%.

Two time constants would be:

1 - 1/e^2 = .864665

and so on....

Oh... and there are other methods you can use to solve the simple RC formula,
but the method I chose is a very general and powerful one worth learning well.

Jon

It's not loss. It's embedded bits of steel later turning to rust. I
could even see the possibility of the particles acting as diodes of
sorts, and could cause noise. Even if thats not true, embedded rust
particles on aluminum elements is not what I would call desired. Could
leave red streaks. Myself, I use the scotchbright pads, "usually
green", and whatever soap is around. MK

Hello

I am trying to come up with a "balcony railing mount" for use with a Ku-band dish plus dish mover. I have searched google and have not found any online dealers which sell such a mount.

My apartment is on the 11th floor with a railing on the outside patio, approx circumference is 12 inches (around).

My apartment landlord is being "difficult" with roof access and wants me to subscribe to the apartment complex's own dish system.

I simply want FTA programming.

If anyone knows where I can find a balcony railing mount (or similar) please let me know

thanks

Prompted by the lack of a definitive response, I did a little web research. A wide variety of industries (e.g., cookware and window frame makers) routinely recommend cleaning aluminum with steel wool. Notably, however, the FAA seems to prohibit it on aircraft. One newsgroup poster (an EI, which would be a bad environment for corrosion) said he had direct -- bad -- experience, and would never use steel wool on aluminum again. So it looks to me like the jury is still out. Maybe it's ok if you live in an environment that's pretty benign with respect to corrosion, but a bad idea if you live close to the ocean. I don't claim to know, and I've never felt the need to clean outside aluminum, so it's just curiosity to me.

Necessity is the mother of invention. Through the years I have made great friends with metal fabricators to develop "one-off" mounts. Sketch and measure the area for mounting and you will be surprised at the innovative methods fabricators will come up with for attaching your system!

Email a digital photo of the area with your city and the direction the photo is taken and I could make a few suggestions.

> And whence the number 63%?

Suppose you are trying to fill up a box with balls. However, for some strange reason, you've decided that each time you throw in balls, you'll throw in 1/2 of the balls that will fit in the remaining space.

At the first second, you have 1/2 the balls. Next second, you'll have that plus 1/2 of the remaining space, which is 1/2 + 1/4 = 3/4. The third second, you'll have that plus 1/2 the remaining space, ie, 1/2 + 1/4 + 1/8 = 7/8...

So, the number of balls at any time t will be:

B(t) = 1 - (1/2)^t

Thus, after 3 seconds, there will be B(3) = 1 - (1/2)^3 = 1 - 1/8 = 7/8, just like above.

Now, apply that same reasoning, only instead of using the ratio 1/2, use the ratio 1/e (since we are applying arbitrary rules)

Then

B(t) = 1 - (1/e)^t

After the first second, you'll have

B(1) = 1 - (1/e)^1 = 1 - 1/e = 0.632 (that is, 63%)

Strange coincidence, isn't it? It happens because when you are charging a capacitor through a resistor, you are throwing balls, in the form of charges, into a box (the capacitor), and the number of charges you throw at any given time (the current) depends on how many charges are already on the capacitor (the voltage).

Each step of the formula above is one time constant, RC. By dividing out the RC, you can get the answer given seconds, ie

B(t) = 1 - (1/e)^(t/RC) = 1 - e^(-t/RC)

Where B is the percentage 'filled' the capacitor is (ie, what percentage it is of the input voltage).

Why is 1/e used instead of 1/2? That has to do with the fact that we must have a continuous solution, not a solution based on ratios of existing values; the rate of change of the current (ie, how many balls we throw in per unit time) is proportional to the voltage remaining, which is continuously changing. Using 1/e instead of 1/2 allows us to generalize to this, in the same way as the compound interest formula allows us to compute 'continuously compounding' interest.

> each time-constant period?
>
> And whence the number 63%?

Let's try another way. You can actually experiment yourself.

Take a 1000uF electrolytic cap and charge it up to +5V, then disconnect the power supply. Put your voltmeter on the cap terminals and read +5V. Now take a 10k resistor and put it across the terminals as well. The cap discharges slowly. In the first moment the discharge current was 5V/10k = 0.5mA. With this current the cap would be discharged in 10s, this is the time constant "tau" = RC

But since the voltage is dropping also the discharge current drops. Now you can use a stopwatch and read the voltage after 10s and you find it to be 1.84V, which is (1-0.624)5V. So this is where your 63% come from. Since we are discharging, the value is 37% of the initial voltage. You can also note down the values for 20s, 30s etc. until your meter has no more resolution and find the corresponding values for multiple time constants.
BTW you do not need to do this experiment yourself but use a simulator or solve the equations others have already written in their answers.

All you need is a 5 gallon bucket, a bag of cement, and a few feet
of appropriate diameter fence post. Just be sure to molest the bottom
of the post such that it's not round anymore before you stick it in
the cement.

```

Actually, being on the 11th floor means squat. The window sill is on the 11th floor, too, but it's part of the outside of the building and you're not legally free to attach a dish to the window sill. In reality, the railing is legally an exterior part of the building like an exterior wall or the roof. What's on the inside of the railing is balcony, and the railing begins the outside of the building.

> the voltage "know" that it should be increasing exactly 63% during
> each time-constant period?
>
> And whence the number 63%?

The voltage knows nothing about how it's "supposed" to behave. It just does its thing without a care in the world.
The thing it does though, will always result in exactly the same voltage shape, because with a fixed R and C and supply voltage it can do no other.
As the C voltage grows, the voltage across the R must drop. If the R voltage drops then the charging current must drop. If the charging current drops, then the C voltage must rise at a slower rate, ... and so on and so on ...
Everything slows down more and more as time goes on. A bit of thought and you'll notice that the C can never actually charge exactly to the supply voltage.
As this RL RC (dis)charging process must always result in this particular shape or curve and this quite 'natural' curve turns up across all branches of science, engineering and finance, it wasn't long before the mathematicians found they could usefully model, or describe the curve accurately, using an equation based on the 2.718 "e" value used for working out 'natural' logarithms.
Hence the maths numbers and formulae that are taught are a good descriptive model or analogue of what's happening in the circuit but have nothing to do with the actual circuit workings.
Be wary when relying purely on maths models. They confer 'expertise' into how something works, without offering 'understanding' of how something works. The difference can be crucial.
regards
john

## 366. NOT ifwtech.com

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-12 12:57:25 UTC
From: "Ian White, G3SEK" <G3SEK@ifwtech.co.uk>

Sorry for the bandwidth, but...

Please note: my former ifwtech.com domain is NOT under my control any more.

I lost that domain name 3 years ago, due to my ISP's careless failure to renew it. Fortunately I also had the ifwtech.CO.UK name registered, and have been using that ever since.

What's new - and nasty - is that ifwtech.com has now fallen into the hands of a company that has reactivated it as a gateway to popup ads, premium-rate phone services and other dubious activities. The really nasty thing is that this new site uses keywords like "yagis" and "power amplifiers", so it can easily be mistaken for something of mine. It most definitely isn't.

Please check, in case you still have any old web links pointing to ifwtech.com. Now would be a *very* good time to update them to ifwtech.CO.UK !

Once again, sorry for the bandwidth... but be warned about other domain names that may have been reactivated as the "evil walking dead".

Source record: 88562

Alan Horowitz wrote:
"---how does the voltage "know" that it should be increasing exactly 63% during each time-constant period?"

The rate of growth or decline is natural as the circuit response is non-variable and operates on the energy flow in the circuit at the instant. This rate depends on the state of charge in the capacitor while the capacitor is charging. Rate of capacitor discharge depends on the charge remaining in the capacitor. It is steadily (exponentially) declining during discharge.

The time required to charge a capacitor to 63% (actually 63.2%) of full charge, or to discharge it to 37% (actually 36.8%) of its initial charge or voltage is defined as the "time constant" of the circuit.

A search on "time constant" will produce many colorful illustrations.

Time constant is the time in seconds for a capacitor to charge up to 63% of the applied voltage, or the time it takes a fully charged capacitor to discharge from 100% down to 37% of full charge.

Time constant is the product of R (in ohms) times C (in farads) in an RC circuit.

Time constant is the quotient of L/R with L in henries and R in ohms in an RL circuit.

Epsilon is a number approximately 2.71828 which is the base of the natural, Naperian, or hyperbolic logarithms.

There is a natural rate of growth or decline caused by growth or decline as a constant percentage of size at the moment. It is epsilon.

As an example of natural decline, the quantity of charge (q) remaining in a capacitor after current has been flowing out for (t) seconds is:

Qo times epsilon raised to the minus t/CR power.

Where Qo is the initial value of q.

Voltage is proportional to charge, so V at any time can be found by substituting Vo for Qo in the formula for q.

Best regards, Richard Harrison, KB5WZI

That's essentially what the Hy-Gain AV18HT HyTower is- a 50' tower with
stubs to make it resonate on 80-10. They say with a loading coil at the
feed it also does well on 160. You should be on the right track here,
though I'd likely do separate verticals for 6m, 2m and UHF. There was a
dandy 2m/440 collinear vertical in QST last fall that's working fine for
me, and I've had good results with a copper pipe 6m J-pole in the past.

You also can't tell someone that the dish can't extend into "common area airspace" Airspace is unfortunately controlled by the FCC, now, a WALKING area, or other public/common area space yes, but not "airspace". You can write it into your CC&R's all you want, but it doesn't make them legal, and that is what the FCC is covering. If the dish is mounted on the owners exclusive use area, it can extend up above the height of the fence if that is what is needed for them to use it (provided it doesn't intrude into another units exclusive use area, or any common area). Just because people don't like to SEE it, doesn't mean you can ban being able to see it. Sure, it's better NOT to see it (dishes are pretty ugly), and it's nicer of the owner to abide by the requests of others, but they don't necessarily HAVE TO. If it is necessary to extend above a fence to receive signal, and it isn't intruding into common space (walkways, lawns, someone elses balcony, etc..) then you have no say.

I'm disappointed, Wes. I was expecting
a rational response, not this baseless
accusation. There was nothing pejorative
in my response. Apparently, intellectual
honesty is not one of your assets.

Alan,

John Popelish got a good start with "e is a natural constant that has
some very sweet
properties in many applications of mathematics, and simplifying..."

Then, it looked as thought John Jardine was going to steal my thunder with
"the voltage knows nothing about how it's "supposed" to behave. "

This could resolve to a mater of faith Alan.

Indeed, the voltage/current "knows" nothing.

After observing what happens in such circuits, "we" (those who must
understand all things) very carefully examined what was going on and
"discovered" that there were mathematical expressions or equations which
would model what happens in nature. "We" came up with theories about what
was going on and what was causing it to happen. "We" then found ways to
make the math fit reality. In the case of time constants, we have a natural
phenomena which is very nicely described by the equations stated elsewhere
in this thread (the 1/e thingy). It is just like the F=MA equation. "We"
discovered that the force applied to a mass is equal to the mass times the
acceleration. The Mass knows nothing about force, acceleration or
mathematics. We found that this math describes nature.

It is exactly like a model airplane (or whatever). We make the model to
look like the real thing. The real thing knows not of the model that we
built, but if we did a good job, I or you can now look at the model and
"know" just how the real thing looks.

The math behind all of our sciences is just like this. *WE* found math
which models reality and because we did such a good job, we can now "do the
math" and "know" how the real thing should behave.

To be a little more specific, in the case of the time constant. we have
theories about current flow, charge, capacitance, inductance magnetism and
resistance which are borne out by countless experiments and then by
subsequent usage. These theories have all had mathematics fitted to them,
and by golly everything fits. We can now plug-in values to equations till
the cows come home and holy-cripes! The real thing does just what the math
predicted. Based upon the properties we have observed for each type of
component, this math works out such that this 1/e thingy fits just right.

In other words, the answer is: "It just does!"

Reminds me of Galileo writing in "The Assayer," saying:

"Philosophy is written in this grand book-I mean the universe-which stands
continually open to our gaze, but it cannot be understood unless one first
learns to comprehend the language and interpret the characters in which it is
written. It is written in the language of mathematics, and its characters are
triangles, circles, and other geometric figures, without which it is humanly
impossible to understand a single word of it; without these, one is wandering
about in a dark labyrinth."

(By the way, to anyone who has NOT actually read The Assayer from beginning to
end, I highly recommend it!)

Mathematics is a wonderful world all of its own, independent of nature, yet
where it often turns out that insights in that world happen to happily suggest
relationships found in this world and where proper deductions there imply proper
deductions here. The language is sufficiently rigorous that someone two
millennia before me can describe a circle using it and I can read it today,
knowing absolutely nothing about their lives, their fads or interests, their
politics or style of dress, and come away with exactly the same image in mind
with exactly the same deductive power. In short, mathematics is a quantitative
language that speaks across culture, time, and place. And there is nothing we

have to compare with that.

The processes of science work to achieve a relatively objective process that works well. It requires the use of objective language sufficient for rigorous quantitative deductions (by anyone adequately trained in the language) to specific circumstances, insists that such language both explain past results well and (more importantly) also make accurate and repeatable predictions, requires quantitative prediction for discernment, and requires time and patience for the resulting critical opinion of others skilled in the field to arrive at a consensus. But mathematics *is* a key part of this objective language used in science because of its demonstrated congruencies with nature.

>In the case of time constants, we have a natural
>phenomena which is very nicely described by the equations stated elsewhere

>discovered that the force applied to a mass is equal to the mass times the
>acceleration. The Mass knows nothing about force, acceleration or
>mathematics. We found that this math describes nature.

One thing to keep in mind is that ideas like "density," a useful relationship between volume and mass, are truly discovered through hard work and through trying to find some kind of useful discernment regarding sinking and floating. One doesn't just naturally _know_ about density, as our direct senses tell us nothing of the kind. It's discovered and then taught and learned. And such relationships are about parsimonious tools for prediction.

And yes, we have been fortunate that some math describes some nature.

>It is exactly like a model airplane (or whatever). We make the model to
>look like the real thing. The real thing knows not of the model that we
>built, but if we did a good job, I or you can now look at the model and
>"know" just how the real thing looks.

It can also be that the model ignores some of the unimportant details of the "real thing" and still be quite useful. Or that it ignores some important details, but that so long as we keep those boundaries and limitations in mind the model is still quite useful for many other things.

I like your example.

>The math behind all of our sciences is just like this. *WE* found math
>which models reality and because we did such a good job, we can now "do the
>math" and "know" how the real thing should behave.

We can also disappear into the mathematical universe and discover brand new relationships there and have some expectation that where such new territory is true there, it will probably be found true in the real world as well. One can make important discoveries using mathematics and use them to suggest what can be searched out and found here. Surprising, at times.

>To be a little more specific, in the case of the time constant. we have

>In other words, the answer is: "It just does!"

Yup. In the capacitor case, for example, I idealized it as a simple differential equation. Real capacitors are more complex, but the ideal is often close enough in practice to be useful.

Enjoyed seeing your thunder!

Jon

Hi Tom,

Well considering "virtual bi-directional coaxial phasing/delay line."
in isolation, I find it rather un-remarkable (if this is in fact an
accurate quote). Afterall, each and every aspect is perfectly
achievable by any NEC modeler on the market (even ones with less than
standard GUIs).

Virtual? That is the first approximation of modeling from the outset.

Bi-directional? There is nothing to impede direction in any
interpretation.

Coaxial? This is merely a tedious exercise in construction.

Phasing/delay line? This follows of necessity and application of ANY
design of wire described within ANY modeler.

Is there something special about the combination of the isolated terms
that invalidates their being realized in ANY modeler? That is, is
there something special about a "virtual bi-directional" anything that
is not achieved separately as "virtual" or "bi-directional?"
Further, is there some unique entity of "bi-directional coaxial" that
fails resolution in a model? Or is "coaxial phasing/delay" unknown in
the art of modeling? I see nothing original and foreign about
"phasing/delay line" within the practice of modeling.

Does this arcane art only appear at the third order of terms? That
is, is there something unachieved by modelers in regard to "virtual
bi-directional coaxial?" This goes again to the simple tedium of
description of the various wires to construct one - tedium is not
unique unfortunately as anyone who has watched the Republicans
unsuccessfully try to pass their own agenda within their own
majorities can attest.

Perhaps it arrives at the fourth order of chaining terms. However, at
this point it becomes regressive evidence of that same tedium, which
can be simply resolved without a dictionary if only one were practiced
in the art of modeling. Let's see, there are 5! ways to de-convolve
this conundrum and none appear to be outside of the scope of rendering
in a model. As such, it appears to be through the poverty of the

carpenter rather than of the tool.

Barring testimonials, I may be wrong and my ignorance be disclosed by evidence. Or some may call me stupid but not Ishmael ;-)

Can you quote a court decision of FCC ruling that declares otherwise?
Property rights, at least here, include all EXCLUSIVE USE areas, which would include the balcony of an 11th floor apartment. There is NO "common area" around it, but the WALL behind it IS considered off limits, because it is a "structural" piece of the property that could be affected by drilling holes in it. Although I know of a few condos and apt's here that would allow it anyway, because they aren't uppity assholes when it comes to satellite systems. lol

I used to manage apt complexes, and condo's, and still have friends that manage, own and operate, and/or serve as repair staff at several local condo and apartment complexes, and they are all aware of the rules, and they allow the mounting of dishes on the balconies, provided they are not bordered by public area (walkways, yards, play areas, etc.), and typically a multi-level complex is NOT going to have anything outside of the balcony, unless they have a balcony that happens to attach to the main walkway leading to stairs/elevators (I do have a couple of friends that live in apartments that have this style balcony, and they are not allowed to mount on TOP of the rail, or on the OUTSIDE of the rail, where the dish would extend more than 2" past the top railing out into the walkway (and they wouldn't WANT to anyway, because someone would likely mess with it). Their dish is mounted on the balcony, close to the wall, where nobody can get to it without climbing onto their balcony to do it.

I'm sure with enough money, an asshole landlord or condo association might TRY to battle this type of installation, but I can almost guarantee that the owner would win. If it's already been tried in court, I'm sure we can find the outcome somewhere. If you find one, let me know. I'm not up to searching, as I have more important work to do right now. :)

I'll mount my dish anywhere I damn well please, and if they don't like it, they can take me to court, where I'll fight to the end (IF I were in a condo, especially one that I BOUGHT AND PAID FOR). Fortunately I'm in a house, and i can do whatever I want. i could mount a big 50 foot dish in my front yard if I wanted to (God would that piss off the neighbors, but that's too bad for them. I hate their purple and pink painted houses, so we'd be even. LOL).

"Fat Bastard" wrote:
> Can you quote a court decision of FCC ruling that
> declares otherwise?

No. I base our differentiation between "Balcony" and
"Railing" on our CC&Rs. Our CC&Rs clearly define
the "balcony" to stop short of the railing. If the FCC's
rule overrides that definition, please show me in what
document or ruling.

> Property rights, at least here,

Where is "here"?

> include all EXCLUSIVE USE areas, which would
> include the balcony of an 11th floor apartment.

And you continue to side-step the definition of
"balcony" and to include the railing by inference.
Where is "railing" included in the definition of
a "balcony"?

> There is NO "common area" around it, but the WALL
> behind it IS considered off limits, because it is a
> "structural" piece of the property that could be affected
> by drilling holes in it.

That "structural piece of the property" is by definition
"Common Area" - it is NOT part of the Unit but part
of the commonly owned building (in the case of condos).
So are the walls on either side of the balcony common
area, and so are the ceiling and floor of a balcony
common area. If you would read the CC&Rs of those
buildings you "managed", you would know that the
balcony portion of the "Unit" is merely an airspace, as
is the rest of the "Unit". The owner buys an interest in
the structure (i.e. Common Area) and an interest in an
airspace known as the "Unit". Thus, he has control of
the use of that airspace. The question at hand is
whether the railing is part of that airspace or whether it
is part of the structure. Our CC&Rs say it is part of the
structure, and therefore part of the Common Area.
Whether it is Exclusive Use common area you have yet
to show because a window sill is common area that is
exclusively used by the adjacent unit, but it can't be used

to mount dishes. So what's the difference between a
window sill and a railing when it comes to classification
as Exclusive Use common area? I say there is none,
because a "railing" might be built like a low wall and an
extension of the building's facade, not a framework of
metal bars as you probably imagine. In such a case,
even you would say that the outer surface that low wall
was part of the exterior of the building and not part of the
Exclusive Use area - even on the 11th floor.

> when a current just starts flowing into a RL or RC circuit, how does
> the voltage "know" that it should be increasing exactly 63% during
> each time-constant period?
>
> And whence the number 63%?

First, I should make a few corrections to what you've said. The voltage doesn't increase 63% during each time-constant period. If it did, it would become 1.63 times its original value after the first period, then 1.63*1.63 = 2.66 times, then 1.63^3 = 4.33 times, etc. The voltage would increase forever, and the circuit would fry itself.

I'm assuming you're talking about a battery connected to a resistor and capacitor (or inductor) in series, or similar circuits. In the case of the capacitor, the voltage across the capacitor starts from zero, and in the first time-constant period, the voltage across the capacitor rises to 63% of the voltage across the battery. In each time-constant period thereafter, it increases by 63% of the difference between the battery voltage and its previous voltage.

Sorry if you knew this already, but it's hard to tell from just reading a post.

It also isn't exactly 63%. The number predicted by theory is 63.212055882855767840447622983 85 ... %. But that number will not be exact either, due to the fact that the models which predict it assume perfect wires, perfect resistors, etc., which is never the case. At some point one has to round.

Let's examine such a circuit at at some time after the switch has been flipped. We'll call the voltage of the capacitor at this point V and the voltage of the battery E, the value of the resistor R and the value of the capacitor C.

The voltage across the resistor is E-V, making the current through it (E-V)/R. The charge on the capacitor is CV. If the capacitor were fully charged, it would have a charge CE. That means the capacitor needs CE-CV more charge to be fully charged. If the current through the resistor continued to flow at its current rate, the time it would take to supply this charge would be CR. This time is called the time constant.

It's crucial to notice that the time constant we just computed does not depend on how far the capacitor has been charged. At any time, it is correct to say that if the current through the capacitor would only stay the same, it would be fully charged after an amount of time later given by the time constant.

Of course, the current through the resistor will not continue to flow at its current rate. As capacitor is charged, the voltage across the resistor decreases, and with it, the current.

Let's pretend the current really does stay constant for a small fraction 1/n of the time constant, that is, for the short time CR/n. In this time, the capacitor's voltage would increase by 1/n of the difference between the battery's voltage E and its present voltage V. The voltage E-V across the resistor would decrease by the same amount, making it (1-1/n) of what it was before. After one time-constant, the voltage across the resistor would have decreased by the same ratio n times, making the voltage across the resistor (1-1/n)^n times its previous value.

This all still an approximation; the current doesn't really stay constant for any length of time. But if CR/n is very small, the drop in current is insignificant. If we choose larger and larger values of n, the answer we get becomes better and better. If we choose an extremely large n, the error will go away with rounding, and we will get (1-1/n)^n = 0.3678794... . And if the difference between the battery voltage E and the capacitor voltage V is 37% of what it was before, that means that the voltage of the capacitor increased by 63% of that difference.

The reciprical of 0.3678794..., 1/0.3678794... = 2.7182818..., appears in the answers to a lot of problems, and so it has been given a special name: "e." It is near [n/(n-1)]^n, for large n. We can simplify this formula even further by replacing n by m+1, making it (1+1/m)^(m+1), and dividing by (1+1/m), which is very near 1, to get (1+1/m)^m, for large m.

While in principle one could compute e by choosing a very large n, in practice you need such a large n to get a correct answer that the calculation that ensues becomes tedious. But, using the binomial theorem, we can find:

(1+1/m)^m = 1 + m(1/m) + [m(m-1)/2!](1/m)^2
+ [m(m-1)(m-2)/3!](1/m)^3 + ...

(1+1/m)^m = 1 + 1 + (1-1/m)/2! + (1-1/m)(1-2/m)/3! + ...

(1+1/m)^m ~ 1 + 1 + 1/2! + 1/3! + 1/4! + 1/5! + ... = e

We can do a similar calculation to find a series for 1/e from "near (1-1/n)^n for large n." It all works out the same, except that we're dealing with powers of (-1/n) instead of (1/n). Terms that had odd powers have their sign flipped:

1/e = 1 - 1 + 1/2! - 1/3! + 1/4! - 1/5! + 1/6! - 1/7! + ...

or

1/e = 3/3! - 1/3! + 5/5! - 1/5! + 7/7! - 1/7! + 9/9! - 1/9! + ...

1/e = 2/3! + 4/5! + 6/7! + 8/9! + 10/11! + 12/13! + ...

1/e = 1/1!/3 + 1/3!/5 + 1/5!/7 + 1/7!/9 + 1/9!/11 + 1/11!/13 + ...

With just the first two terms, which you can add in your head, you can get 1/e accurate to two significant figures.

i hads a similar argument with my old landlord . My problem was that my balcony didnt face south. i got one of my neighbours to let me use their balcony , since i was on the 1st floor.
I then attached my cable run from his apt. to mine to the existing cable lines.
They threatened and threatened and when it came push to shove they couldnt do anything. I took a nice printout of the FCC regulations and dropped it off ;).

My suggestion is that you give up some balcony space and just mount in on a concrete block. That way no one can fuck with you. Just cover it woth a garbage can or garbage bag.

Good Luck

PS: Doesnt matter where you are as long as your in the US

## 403. Stupid question of the day (SQOTD)

I just moved from DM79 to EM17. In Denver, I could put up 1 big inverted V for HF. I selected the Van Gordon "All Bander" and a LDG Z100 autotuner. Worked nice.

Now in Wichita, KS I don't have room for anything bigger than the 134' all bander and I'm without a tuner. I can, however, put up many antennas. (lotsa trees around)

Yesterday I trimmed my all bander until it was 25' per leg shorter and resonated on 40m. It also looks good now on 17 & 10 meters. I put up an inverted V for 20. Using a coax switch, I can switch between the two, giving me 40, 20, 17 & 10.

I'm starting to wonder if multiple antennas via an antenna switch might be the way to go.

I'd like 80 meters but the only area that can fit a large dipole like that is already taken by the all bander so an 80 meter dipole would either have to be a loaded vertical or a loaded dipole. I've got room for a 40' dipole - no larger.

30 & 12 meters do not interest me but 15 does - I'm thinking maybe I'll add 15 meter elements to my 20 meter inverted V.

My question - Am I right thinking that an antenna farm with resonant antennas would outperform a single large dipole and a tuner? My guess is yes.

Also, anybody got good plans for an 80 m inverted, loaded V antenna? Would it be better to put the 15m dipole on that antenna vs the 20m V?

Hi,

To pick up a 137 MHz signal from wx satellite (POES), are the discone and quadrifilar helix antennas similar, I mean, they are different in design but for the rest ?
Are they both omnidirectional and are they both able to change automatically the elevation and azimuth to the satellite direction without interruption and without requiring a rotator ? or only the helix provides this capability ?

Thanks in advance

A discone is a wideband, upside down, vertical monopole, essentially. It has poor coverage at high elevations. It is omniazimuth.

Why would you need a discone? It's chosen for its bandwidth, and you don't appear to have this as a requirement. Also its fairly good sized, even for the skeleton ones.

The Mothers works very well depending on how bad the aluminum is gunked up to start with. Mainly it a finish polish. I tried this but it was cleaning to a degree I could not justify. Way to much elbow grease for something that was going to be "tarnished" again soon and not cleaned for years.

Lots of info on building antennas. If you are interested in beams you will soon find you can roll your own with only slightly more effort than it takes to assemble a store bought antenna. You may find it is not a lot cheaper to build your own unless you have a cheap supply of material. I used to belong to a CB club in the ealy 70's that built Yagi antennas for its members. There was an Al extrusion mill nearby and we could buy defective/blmished pieces for pennies a pound. Most expensive part was the irrigation pipe boom. Think it cost about $30 then. Local feed and seed had them on a rack outside. If the store was closed we would get one off the rack and slide an envelope with the money under the door.

Make the antenna all one piece 1/2wavelength long and feed with a gamma match. You can Google plenty of info on this.

Discone is not the right antenna for this app.

QF helix is good, so is a 2 turn Kraus helix, or a cp patch.

Crossed dipoles in quadrature acceptable in most cases too.

>
> larry
> kd5foy

==========

Larry, you must be joking!

A 6-inch rod at the end of each (truly) surface radial will have the effect of increasing the length of each radial by 6 inches. Just by looking at them, it can be judged the effect on performance will be absolutely negligible.

At HF, adding 6-feet rods will have the effect of increasing the length of the radials by about 6 feet. Again, the difference in performance will very likely not be detectable.

It depends to some extent on how long are the radials before you start adding the rods.

With true surface or very shallow buried radials you can forget about resonant lengths.

To make a noticeable improvement you will have to double the number of existing radials - and then only when the number of existing radials is less than about a dozen.

If you like amusing yourself with simple numbers, to observe the behaviour of sets of shallow-buried radials, download in a few seconds program RADIALS2 from website below.

Why not have 1 feedline - and ' fan out ' several dipoles from that one
feedpoint.
then you won't even need the coax switch

That is patently false, and can be easily demonstrated. The transmission line model in NEC (and EZNEC) is a linear network which is completely bidirectional.

> . . .

I think some doubt is warrented about both Chuck's measurement ability (which led him to conclude that his antenna has more gain than theoretically possible) and his modeling ability.

In September 1997, Chuck sent me the model he created with his pirated copy of EZNEC. Among other problems, which I pointed out to him at that time, were wires which intersected at other than a segment junction, and

a wire which was entirely inside another wire, which causes NEC-2 to give unpredictable and wrong results. (Such errors are now caught by EZNEC 4.0's Geometry Check, and a model with those errors wouldn't run.) This, along with more of the history of his attempts to fit his claims to modeled results, can be found by going to http://groups.google.com and searching the archives of this group for the articles with the subject "raibeam antenna models". There, you'll also find my modeling results for the "Raibeam" and a restatement of the offer I made Chuck some time before, as follows (from my posting of September 23, 1997):

> I made Chuck an offer a while back, as follows: That if he has the
> Raibeam tested at a certified antenna range and the results show a
> free-space gain of at least 5.5 dBd (7.65 dBi) with simultaneous 25 dB

> hasn't taken me up on the offer.

Although I'm sure the cost of such a test is much greater than it was when I made the offer, I'll still honor it. Still not interested, Chuck?

I should also note that a number of professional (real P.E.) and nationally known broadcast engineering consultants are among the users of EZNEC software. It's routinely used for the design of AM broadcast antenna arrays.

When you put a bunch of resonant antennas in close proximity and feed them with individual transmission lines, you really have one antenna with multiple feedpoints. The antennas couple to each other and affect each other's patterns and feedpoint impedances. The higher frequency antennas are, in general, the most affected.

Where you have the room, the advantage to having individual antennas is that you have control over the radiation pattern on each band. When you feed a single antenna on multiple bands, you have to take what you get (although it's easy enough to predict with reasonable accuracy with a modeling program). Otherwise, there's no other real advantage to individual antennas. And, as I mentioned, when the antennas are close to each other, you'll still get distorted patterns on some bands.

Not in the minds of users, or to
those who made confirmation
indepently.

> and demands that your proof is available only through
> a privileged knowledge.

Knowledge comes from experience...
anyone can achieve it if they truly had the
desire.

Getting off one's butt and performing
experiments works wonders in this
regard... :)

> However being ignorant is not the same as
> being stupid.

Agreed.

> The onus is upon you to show (resolve ignorance or
> exhibit it in your own thinking - there are no third options) how your
> claim is substantial - testimonial is insufficient.

Let me suggest, the onus is on you to
prove the claim is without substance
since you are the one making the
allegation. The design is time tested,
and I tire of closed minds.

If some folks wish to remain ignorant
in this regard, it's their loss, for they
only deny themselves a better way.

I have more important concerns in
my life do deal with now.

Correct translation -- might makes right.

I know people in this situation who have gotten legal opinions
that they have the right to mount such devices. However they know that
there is little defense against the retaliation that was likely to
follow. Again, the money is on the side of the property owner.

> each time-constant period?
>
> And whence the number 63%?

It just turns out to be 63% if you add up all
the little voltage changes on the capacitor as it
charges during one time constant. The short basic
program below uses 10000 samples and keeps track
of the resistor voltage at each step and then prints
out the final capacitor voltage of 63%. The accuracy
can be improved by taking more samples. Change time
to a smaller value for a better approximation.

```
Voltage =1
Resistance =1
time = .0001
Limit = 1/time
For n = 1 to Limit
Current = Voltage/Resistance
Voltage = Voltage - (Current*Resistance*time)
Next n
Print "Capacitor voltage = "; (1-Voltage)*100;"%"

'Answer = 63.2139444%
```

Hi Chuck,

That is about as funny as when Art appeared here proclaiming the
marvels of his new invention - and then telling us it was our
responsibility to prove his claims. Can you guess how many years ago
that was?

I'm afraid you are in line behind cfa claims, eh claims, fractal
claims and the notable efficiency per unit length claims.

But as you have more important things to do, one wonders why you spend
so much time with these trivial issues?

'J.C.',
That's one of those "it depends" questions. It depends on if the loop is mounted vertically and can be 'pointed', or horizontally. Then it depends on how high it is above ground. So, the 'best' anyone can tell you is that there will be a difference, but not what that difference will be. I like loops and don't particularly care for verticals, so I think you'd see some improvement (that's scientific, ain't it? LOL)...

OK Roy, I well understood.
I suspected well this purpose due to its vertical polarization. In fact I
was misleaded by the short radials placed at 45 deg on top. But it is common
and that doesn't differ from a ground plan vertical design, excepted it
offers a large bdw....

Thanks

No; the tuner has fairly good QF components: there is a reason your tuner has no huge fans or heat sinks.

Some lost as heat in coax from mismatch insertion loss. Much lost from ground losses; some power now goes straight up rather than at lower elevations.

Hi Ken:

On 1.824MHz, 4.5 db of your power (3db equals 1/2 of the power) is lost in the feedline. I know that 450 ohm line is supposed to be so low loss that it doesn't matter, but a 80m dipole on 160m presents such a very bad match that even open wire line has loss. I would make your antenna as showing a load of about 10J -1250Ohms. Don't feel bad if you were feeding this with coax the excess loss due the miss-match would be over 20db. The 4.5db doesn't include the loss in the coax balun, and the tuner. According to the ARRL review of tuners on 160 with a SWR like that 25% of the power is lost in the tuner. These numbers were derived from modeling the antenna with EZNEC and the TL program that comes with the ARRL handbook. Other people with slightly different models will get slightly different numbers but the bottom line is a 80m dipole is a very bad antenna on 160m. You could be losing 1/4 of your power in the tuner and well over 1/2 of what's left in the feed line. But if its all you have the use it.

|
|Where does my 100w go? is it lost as heat in the tuner?
|(my guess) Is it lost in the feedline due to high SWR at
|the apex?

Using readily available tools, Multinec, XLZIZL.xls and TLDetails.exe,
all available at www.qsl.net/ac6la I computed the following.

Two wires, fed at the junction with a split source:

Wire 1 coordinates (ft):

End 1 End 2
X Y Z X Y Z
0.000 -55.285 10.000 0.000 0.000 33.000

Wire 2 coordinates:

0.000 0.000 33.000 0.000 55.285 10.000

Resonant at 3.922 over average ground. At 1.825 MHz the feedpoint Z =
12.53 -j 1366.

I copied these values to XLZIZL and defined a feed network that
(beginning at the antenna) consists of 100' of Wireman type 553, 35'
of RG-58A, a series capacitor = 1754 pF and a shunt inductor = 2.14
uH.

Now, I don't know whether the LDG tuner will configure itself this way
or not, but this is the optimum solution. The input Z of this mess =
49.19 +j 0.4. SWR = 1.02

XLZIZL gives the total network loss as: ~9.0 dB.

To see where the losses come from we can first look at the L network and see that with the component Q's I used: Qc =500 Ql =200, the loss is only 0.09 dB.

The best way to see the line losses is to go to TLDetails and first select 100' of Wireman 553 and a load Z of 12.53 -j 1366.

The program shows that the total line loss is: 7.7 dB, most of it attributable to SWR. The input impedance of this line section is 5.58 +j2.11.

If we use this value for the load Z and change the line to RG-58A with length 35', we find that the loss is ~ 1.35 dB.

As a sanity check, we add the three losses 7.7 + 1.35 + .09 = 9.1 dB, just as was determined earlier.

So most of the power is burned up in the "low loss" ladderline!

In the last sentence above the words 'in length' should be deleted. The
reference is only to the diameter of the radiator.

I also inadvertantely omitted reference to a photo of two QFH that uses self
phasing and infinite balun feed. In Chapter 22 of Reflections 2, appearing on my
web page at http://home.iag.net/~w2du.

See the photo in Fig 22-1 on Page 22-2. The QFH on the left is the wide-band
video 1.6 GHz antenna flying on all TIROS - N, NOAA polar orbiting wx
spacecraft.

Incidentally, the Astro Electronics Division of RCA designed and built all
TIROS spacecrafts 1 through 9, and all TIROS - N spacecrafts from 1973 thru
1986, when RCA was taken over by GE, and then sold to Lockheed, which has built
the TIROS-N's since the takeover. I was the lead engineer developing the QFH
antennas that are flying on all TIROS - N spacecrafts. I was also the sole
engineer who developed all the antennas flying on TIROS spacecrafts 1 thru 8,
and the 137 MHz 2-element phased array that transmitted the W XAPT signals on
TIROS 9.

Hate to break the news, Walt, but it happens very, very often. Even years ago, when I was doing some consulting work on a patent case and read a couple of hundred antenna patents, there was a great deal of pseudo- and voodoo-science in issued patents. These days, it's rampant.

My favorite example is US patent #6,025,810, "Hyper-Light-Speed Antenna", but I'm sure even this is far from the most egregious.

I have decided to roof mount my Butternut HF2V on a 10 foot tower on my house. It is a tip over tower that should make working on it pretty easy. I'm wondering if I need anything special about mounting the HF2V on the tower itself. I've seen references to a RMK-II kit for roof mounting, but it looks like nothing more than a small tripod and a radial kit. Do I need some kind of sleeze (tubing) to slide the base of the HF2V into? I'm sure some of you have addressed this in the past. I'd like any suggestions. I plan to put resonant radials sloped away from the base and I also plan on guying it with some light weight rope or fishing line above the loading coils.
Thanks and 73,
Terry, WK0F

> definition of what is "balcony".

Technically, yes, but you are probably also aware that any contract that isn't a LEGAL action is NOT lawful, or binding. You can't enforce a contract that is not legal to begin with. Now, I'm not saying that a contract of this nature is or isn't legal, but it is questionable in my opinion, and I'm sure in many lawyers opinions as well (the opposite is certainly true as well though). I personally think that doors and windows to your privately owned "unit" are YOURS, they do NOT belong to the association.

>
> Nonsense. By that logic there can't exist a walkway
> without a railing, or a patio without a fence.

Walkways have never needed a railing, unless they are above ground level (2nd through xxx stories high) and are required for "safety" to prevent someone from falling. A walkway is simply a passage for walking.

Main Entry: walk&#65533;way
Pronunciation: 'wok-"wA
Function: noun
: a passage for walking : WALK

Note, there is NO REFERENCE to a railing. I've never known of a walkway to include a railing as part of the definition. Nor have I known the definition of Patio to have a fence.

Main Entry: pa&#65533;tio
Pronunciation: 'pa-tE-"O also 'p&#65533;-
Function: noun
Inflected Form(s): plural pa&#65533;ti&#65533;os
Etymology: Spanish
1 : COURTYARD; especially : an inner court open to the sky
2 : a recreation area that adjoins a dwelling, is often paved, and is adapted especially to outdoor dining

no reference to a fence here either. (courtyard however does reference being an "enclosure")

My patio has never had a fence around it, and I don't know anyone else with a fence around their patio (unless their patio borders a pool, and they were required by law to have a separate fence around it). Most PATIO's are open areas, possible COVERED, but not "fenced". My patio is OPEN (not covered yet), so i can walk out into the yard anytime I want. My YARD is bordered by a wall though.

Now, note the definition of BALCONY:

Main Entry: bal&#65533;co&#65533;ny
Pronunciation: 'bal-k&-nE
Function: noun
Inflected Form(s): plural -nies
Etymology: Italian balcone, from Old Italian, large window, of
Germanic origin; akin to Old High German balko beam -- more at BALK
1 : a platform that projects from the wall of a building and is
enclosed by a parapet or railing
2 : an interior projecting gallery in a public building (as a theater)
- bal&#65533;co&#65533;nied /-nEd/ adjective

See how it specifically states "and is enclosed by a parapet or RAILING". So, without a railing, it is not really a "balcony", but rather a "patio". :)

> > The railing is part of the balcony (a protective barrier
> > to keep you from falling off said balcony),
>
>
> If your reiterative definition were right, "said balcony"
> would already have a railing - by your definition of
> "balcony" - and it wouldn't need another railing.

I said a balcony already INCLUDES a railing.

>
> By your reasoning, doors aren't structural, either.
> But doors ARE part of the common area - owned
> and maintained by the HOA - and they are certainly
> NOT part of the Unit. Similarly, balcony railings
> are part of the structure - like walls - and not part
> of the Unit.

Doors aren't structural, and I personally would argue whether my DOOR to MY PROPERTY belongs to anyone other than myself. I have exclusive use of my door (if you come and remove my door, or you enter my door without permission, you are TRESPASSING on private property, and are subject to arrest). In your CC&R's you may have a rule that states the door is part of the HOA, and not owned by the property owner, but it would be WRONG, and I would challenge it in court any day of the week. Now, it would be understandable if the door is covered under the HOA agreement as far as

PAINT, or DESIGN goes, but i personally think it's BULLSHIT to dictate what people can do with what belongs to them, and I'd challenge it if i felt the need (if I painted my door and someone complained, I'd tell them to bugger off, and sue me if they feel they have a case). I personally wouldn't go against a particular communities rules on paint colors, or at least not get approval for any color not already on the building, because it's not nice to put some awful color on the building that is shared with others, but on the other hand it's really none of their business, and they don't have to look at it if they don't like it. I'm sick of all these HOA's dictating what people can and can't do, just because a couple of schmucks don't like something.

> > Our CC&R's specifically state that the balcony is
> > EXCLUSIVE USE area. It described COMMON areas
> > as those that can be used by ANYONE, not just the
> > OWNER of the unit. The balcony is PRIVATE PROPERTY,
> > and cannot be regulated by the "public" (commoners). lol
>
>
> Yes, yes. But do your CC&Rs include the railing
> in its definition of "balcony"?

By definition of Balcony, YES. A balcony INCLUDES the rail, by every known definition. it's not a balcony without the rail. It's a porch/patio without the rail. A dangerous one at that, if it's several floors up. :)

> "Structural" does not mean "supportive of the building".
> A railing is as structural as a door or a fence or a window.
> It is part of the physical building that defines the airspaces
> which are units within a condo building. If your house
> (which you said you live in) is part of a community having
> commonly-owned property, the definition of "Unit" may
> be different, but for a condo building containing multiple
> units, the "Units" are airspaces (plus, perhaps, some
> interior walls), but NOT the exterior doors, NOT the windows,
> NOT the patio fences, and NOT the balcony railings.

WRONG. Structural clearly defines "Structure", as in structural stability. See below.

Main Entry: struc&#65533;tur&#65533;al
Pronunciation: 'str&k-ch&-r&l, 'str&k-shr&l
Function: adjective
1 : of or relating to the physical makeup of a plant or animal body
2 a : of, relating to, or affecting structure <structural stability> b : used in building structures <structural clay> c : involved in or caused by structure especially of the economy <structural unemployment>
3 : of, relating to, or resulting from the effects of folding or faulting of the earth's crust : TECTONIC
4 : concerned with or relating to structure rather than history or comparison <structural linguistics>

- struc&#65533;tur&#65533;al&#65533;ly adverb

A railing is not "structural" in most cases. It is decorative, and protective.

Main Entry: 2rail
Function: transitive verb
: to provide with a railing : FENCE

Main Entry: 1fence
Pronunciation: 'fen(t)s
Function: noun
Usage: often attributive
Etymology: Middle English fens, short for defens defense
1 archaic : a means of protection : DEFENSE
2 : a barrier intended to prevent escape or intrusion or to mark a boundary; especially : such a barrier made of posts and wire or boards
3 : FENCING 1
4 a : a receiver of stolen goods b : a place where stolen goods are bought
- fence&#65533;less /-l&s/ adjective
- fence&#65533;less&#65533;ness noun
- on the fence : in a position of neutrality or indecision

Hmm, english definitions of everything seem to support my argument so far. As I said, I would challenge any HOA's on these any day of the week.

> CC&Rs are legal and binding contracts - like any other
> civil contracts - and they are legally enforceable unless
> they contradict state or federal laws - like any other
> civil contracts. They are NOT merely "suggestions".

To me, they are merely suggestions. Unless SPECIFIC (if your CC&R specifically states not allowing the use of the railing to mount anything to, then it's BS, and you cannot restrict it. If your CC&R states nothing can be bolted to the STRUCTURE or outside walls, then that is the WALLS or STRUCTURE of the building, NOT the railing of my personal balcony), it isn't covered, nor is it "legally binding". To be legally binding, it must be legally based, but you cannot impose your "LAW" on someone elses private property.

> And we are discussing "outer", as in outer surface
> of a balcony railing. The inside of a railing is like
> the inside of a door - it's common area, but it's
> Exclusive Use common area. But the *outside* is
> like the outside of a door - it's just simply
> Common Area without exclusivity. And like a door,
> you can't attach things to the outside surface of a
> balcony railing

Balcony is owned by me, it's mine, i'll attach to the railing (part of the balcony) if i want to, inside or out. That's my opinion, and the definition of balcony supports my opinion. The outside of the railing is not common area, because nobody else has access to it (it's hanging out in the air, 20 or more feet above the ground, and is my private, exclusive area, that you cannot enter, or interfere with, without proper authority from me). Again, my opinion, and supported by definition. Some judges may agree, some may not, but I certainly would be willing to challenge it if it came to that.

>
> Our CC&Rs are quite similar to those of others
> in the area which I've seen when it comes to
> defining what is "Unit" and what is "Common Area".
> Your CC&Rs are probably different due to your
> property being a detached house on land that
> solely belongs to you.

I personally don't have ANY CC&R's here. the property I'm on right now is MINE, exclusively, and has no HOA governing it. Some idiots tried to start one up, but nobody would around here would agree to it, so it seems to have drifted away like so many other stupid things people try to do just to force their own beliefs or opinions on others. I was speaking of the rules and regs of the properties we've managed, or worked for, NOT for my own personal and private property that I am located on right now.

I agree with you there, entirely. It does open decades of bickering. Just look at us here. LOL

> assinine they are.

That's great that you put in a community dish, especially if it's provided FREE OF CHARGE, but not all buildings offer that, nor do they all have plans to. Also, by only allowing your own dish/provider you are creating a monopoly, and are infringing on others rights. It is not legal to force anyone to utilize your system if they prefer another. I certainly don't want DTV, so I'd want to install my own dish, provided I have an area where I can do so, which faces the right direction. Now, if you offer every system, cable, dtv, dish, etc., then that would cover all bases. I know that there have been cases where the apt/condo/etc. has tried to force the people to use their provided cable access, and they were challenged, and the owners were allowed to put up dishes. It's not right to limit someone to YOUR preference of providers.

Actually, I've done a lot of pll and control system simulation in
Basic. I really began using an HP 9100 desktop calculator (for
steamship throttle control system simulation), graduated to FOCAL,
then RSTS/E Basic+, QuickBasic, and now PowerBasic.

I agree, C isn't logical. Why this bizarre and ugly hack of a PDP-11
assembler got to be the programming standard is beyond me. We're
paying the price big time.

John

Hi Richard,

It is my opinion - and only an opinion -
that Art's antenna did achieve critical
coupling... and perhaps yet another
case where the model failed to agree
with empirical observations...

> I'm afraid you are in line behind cfa claims, eh claims, fractal
> claims and the notable efficiency per unit length claims.
>
> But as you have more important things to do, one wonders why you spend
> so much time with these trivial issues?

A few hours a month or less is 'much'
time? Surely you jest... :)

In any case, since you have no first-
hand experience with my design, all you
can offer is mere opinion - the antithesis
of fact.

Since my design can stand on its
established record, the onus is on you
to provide something of real substance
- say, empirical data - to support your
opinion.

I'll take your word for it, and apologize. You had claimed long ago that the program was given or sold to you, but for reasons of your own you would never tell me from whom. (Although I certainaly approve of such transfers, I never gained knowledge of whom the transfer was from.) In my posting of Sept. 26, 1997 on this newsgroup, I said:

> I don't generally give support to someone who's not a registered user,
> but in this case I guess it's necessary. (You still haven't sent me

Because you never furnished that information, I assumed that you had acquired it illicitly.

If you'll email me the name or call of the person from which you acquired it and the amount you paid, I'll promptly send you a full refund, in accordance with my guarantee. You're obviously not a satisfied user.

No, you'll have to make the arrangements.

Determine the cost of the test. I suggest that we find someone who is willing and we both can trust to whom I'll send the money the test will cost, as proof of my willingness and ability to pay the test fee if the antenna meets the criteria. Let me know when the test is to be done, and I'll come down and observe. The person who pays will have the legal right to make the results public. I agree in advance to do so if I pay; I expect you to do likewise.

Thank you (various people) for the comments about half sloper attachment points. I think the result is that the half sloper should be attached as high as possible on my small (55') tower. (It is intended for 160-40 meters.)

Ken, K7GCO got bunch of RAIbeams and put them up, wrote glowing review for 73 Mag. He was impressed with the performance and wanted to figure out why is it so. He very carefully inserted dimensions into EZNEC model and could not get agreement. He had to go down to 48. 5 MHz in EZNEC to obtain similar pattern and parameters as real antenna resonant at 51.25 MHz.

So, maybe modeling doesn't "see" the dual driven elements and critical coupling well? It is amusing to see the "experts" defending unmistakability of software (loading coil case etc.)

Yuri, K3BU.us
can we all get alone?

Chuck,

I am sorry to hear that another individual here is allegedly making false statements.

I, personally, wish you well, and I am very sorry to hear about your wife's illness, and wish her a speedy recovery.

I appreciate that you are a professional, and as one professional to another, I want to point out that you are an honorable person. I am of the opinion that we should all show you the proper respect. I am sorry if that is not, apparently, being shown by a very few.

Sierra Vista is a beautiful place, and the Fort has some cool antenna stuff. They might go down below 50 MHz, BTW.

My best wishes to you; been a long time.

73,
Chip N1IR

Some terms of the contract can be invalidated by other laws.
For instance the CC&Rs in the Wsstlake area of Daly City, CA, which
stated that an owner could not sell his house to a person of color.
There is a good chance that FCC rulings supersede most CC&Rs.

I'm sure you're glad, as I am, that Chuck has finally accepted my offer and agreed to have a real, professional test done, after something like 8 years. The results of the test should put to rest any speculation about this issue. I'm looking forward to the test and seeing the test results.

I get feedback from some of my professional customers who have the capability to test the antennas they analyze with EZNEC. They report very good agreement between analysis and measurement. Of course, most of them are real pros in both modeling and measurement. Given the choice of believing their results or Ken's and Chuck's, I go for theirs. Even though you might not consider those folks to be "experts", I do.

But by all means, let's look at the test results -- unless you believe that "critical coupling" results in radiation that conventional test ranges can't detect but hams can. . .

|> MHz.

Fort Huachuca is not located in Tucson, it is located at Sierra Vista,
AZ, approximately 90 miles SE of Tucson.

Some of the capabilities are listed here:

http://www.epg.army.mil/Test_Beds/ATF.htm

As an aside, I have tested under the ARC range and have been to the
top of the "Red Tower" just to look around. Quite a view! I've seen
photos of an M1-A1 tank mounted on the positioner of the "Compact"
range.

Unfortunately, when I was there five years ago, a lot of the equipment
associated with the compact range appeared to be in disrepair.

I suspect that you will have a hard time getting testing done here as
security is a big issue. But I could be wrong.

Maybe there are cases when things don't play as figured? Maybe would be of interest for software author to find out, and if there is a glichand to find the way to accomodate it? Have you figured out how to model loading coil of particular inductance and physical size to reflect the real current drop across it?
Experts said one time that she's flat.

Here we go again, W8JI snotty style?
I just mentioned what K7GCO found, in hope that it might shine some light at the subject and arouse some curiosity about disagreement. If it is inconvenient, than I am sorry to butt in here. I have no intentions to get engaged in pissing contest. Right now I am too busy with new ocean front QTH next to 170 acre Rhombic antenna farm, DR1 design and business that brings livelihood. When I get more time, I will get back to work on antennas, setup test range (across salt water bay) and get into paper models vs. real ones.

Peace!

Yuri, K3BU.us

EZNEC v. 4.0 has a convenient helix creation feature, which allows the user to quickly make a wire model of an inductor. An inductor modeled in this way will show a current distribution very close to that of a real inductor. There are two cautions, however. One is that EZNEC programs prior to v. 4.0.7 had a bug that would create incorrectly sized wire (when creating a helix or loop) if wire diameter was specified as AWG rather than numerical diameter. So be sure to update your program to the latest version by downloading and installing the latest update from http://eznec.com/ez40updates. (You've said you don't read the manual, so you probably aren't aware of these free updates.) The second caution is that turns should ideally be spaced at least several wire diameters apart. I have, however, seen good results with spacings down to one wire diameter. At that spacing, though, EZNEC will overestimate the Q somewhat (that is, underestimate the loss) because it doesn't account for proximity effect.

Source record: 88452

Chip, I have no problem with that, but the PTO has changed in the last few years in how it does things
I read an article a few days ago where companies have gone into their basements to review
old and forgotten patents as litigation between various companies has proved to be a cash cow
for some when reviewing the grammer of patents (claims) and activities of other companies in a grammatical sense.
You should also note that the Justice Department.has added elevated importance( strength) to grammer of claims
in a attempt to curb increasing litigation against the P.T.O..... So things are a changing.
I believe this to be a consequence of the PTO increasing dependence upon the grammer of the claims rather than
the contents as a whole. Remember, lawyers and other reptiles can debate for hours as to what
the definition of "is:":... is, in a grammatical sense. where-as old english law established the original INTENT
as the primary definition .
This difference is why the U,S. has a huge playground for its increasing lawyer population as its politicians
do not seek prior legal aid regarding the blend of ":grammer" and "intent" when making laws. which
the rest of the World does

I hadn't realized that when my GPS got me out of a bit of a jam on my most recent backpacking trip, I had Walt to thank (among others of course) -- the GPS receiver uses a quadrifilar helix antenna. Thanks, Walt!

Walt also gets credit for an important role in developing the weather satellites which bring us such benefits as early warning of the hurricanes that recently went through Florida. I hope your house in DeLand came through ok, Walt!

Thanks, Roy, for the warm words about my connection with the QFH on the wx spacecraft. My work in that area was a love affair, and I was just lucky to be in the right place at the time the space exploration was just taking off.

I'm also lucky about the hurricane situation in Florida. My only damage was losing one panel of screening around my pool. My son Bill, W2WM, has moved into his new house, also in DeLand where I live, and he had no damage at all there. But his house in W Palm Beach, that he is putting up for sale, suffered extensive damage to the roof, causing leaks. However, FEMA came to his rescue by placing a tarp over the house, covering the entire roof until it can be repaired. I give FEMA a lot of credit for the terrific work they're doing to help the survivors of those terrible storms.

Walt

Any contract that has any illegal terms/conditions is NOT legally binding,
just as you noted below. We cannot discriminate against people of color, and
we cannot enter into contract when said contract is illegal in nature. You
cannot enter into contract with MINORS either, for this same reason. It
would be like a drug dealer requiring a contract with his buyer, it just
won't cut the mustard. :)

> Art, you seem to know a lot of what's happening in the US Patent Office.
How do
> you know this? Do you work there? Your 'insider-type' statements seem to
say so.

No I do not work there I am just stating how I see things in Crystal City.
After I retired I did go thru the machinations of patent requests on a
personal basis
where I did everything by myself . This allowed me to discuss things
directly with the PTO
which is something you cannot do if you hire a representitive ( attorney )
or a part of a companyBy doing things this
way you get a keener sense of what is going on and where the difference
between a parallel
circuit and a series circuit can be lost on the examiner. I have also been
invited to PTO seminars
where excuses have been made for irregular procedures because of money grabs
by the government.
I also had a meeting with a military patent attorney where he lamented about
the lessening quality
of examiners that took the easy way out of denying patent requests
presumably because of efficiency drives
and where the military attorney was forced to follow the costly appeal route
with a more than 80% reversal
success rate.
You also now have the U.S. patent office dealing with World Patents so that
even a simple "7" on a drawing
with a slash on it (European style) can throw a patent into a unknown loop
of uncertaincy.
Ofcourse if you are a patent attorney you may well see things differently as
it is your bread and butter
and you recognise hitches ahead of time by knowing the ropes thru experience
plus personal
conversations with the PTO.as to obtaining a patent per present day
aproaches which are very
different from yesteryear..
This is how I personaly view things and it would appear from the media that
many see the Patent Office
as being in a hole from which it cannot extricate itself from given the
present day litigation system.
Mac is a professional in this field and may well provide insights that
totally contradict my perceptions

if he was so inclined.

## 470. Re: Patents

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-15 04:55:28 UTC
From: Andrey <a8421@intergate.bc.ca>
Message-ID: <10mulnpi1478484@corp.supernews.com>
Source record: 88464

I have several patents issued to my name with US PTO. For Antennas. They are not mine, technically. I made the innovations being a consultant to the company, the company decided to patent it. My name is there but the patents are theirs.

One patent is total nonsense. The design was original and practical, the result went into production. Then I wrote a description, drew a diagram. I discussed it with examiner who came over for that very purpose. The examiner was an American, his English better then mine. I did not do the follow up - left the company by that time. The resulting text has very little resemblance to what I tried to say. It is clearly not what I made. It does not make any sense to me. Moreover, I am not sure the described 'device' is possible at all.

It was patented all right - anyone can see it on the Web now.

I show it to my friends sometimes, as object of curiosity.

Andrey

Egads!. You've just given away the secret of Spice Transient Analysis. The
programmers will be calling for you with torches ablaze.
Why is it that if anyone wants to *clearly* explain an algorithm or
sequential idea, they'll use "Basic" or a very Basic looking 'Pseudo-code',
yet most programmes seem written in "C".
It just isn't logical.
regards
john

As when using in terrorem clauses, designed to frighten
someone from taking legal action to recover loss. The classic example
is the signs some cleaners post saying that clothes left over X days
can be sold for charges and need not be sold for actual cash value.
The signs normally specify X days as far shorter than that specified
by law. If the cleaner actually sells the clothes before the legally
required time, he is liable for damages for the entire market value of
the clothes less the agreed-upon cleaning charge.

"Can" and "permitted" are two different things.
A strict interpretation of the CC&Rs permit neither,
but the addition of knobs are overlooked as the doors
originally had only pull handles, and many owners
have installed knobs that match the pull handle.
Likewise, the type of lock is overlooked as the
original lock is no longer made and newer locks
are more secure. No owner is permitted or allowed
to remove the large custom pull handle as that would
cause a major change in architectural appearance
and a loss of uniformity. Christmas decorations,
Thanks Giving decorations, Halloween decorations,
etc, are classed as "temporary decorations of a
seasonal nature", and they are allowed to remain for
a maximum of 45 days - long enough to encompass
all religious and seasonal needs. The goal has been
to avoid permanent changes which some owners could
bitch about but yet to allow individual expressions of festivity
and/or religious observance. So far, things have worked
out well. As with all rules governing a democratic organization,
there needs to be both wiggle room and restraint, and
balancing the two is the mark of a good governing body.

One of the major difficulties with HOAs is that most
condo owners are previous apartment renters, and they
don't know the problems of maintaining real property and
the politics of common ownership. All they know is that
they pay dues, and they assume that is like paying rent -
someone *owes* them management services in return,
and since they are now "owners", they should be allowed
to do whatever they please with everything in sight.
Never does it occur to them that *they* are responsible
for the upkeep of the property, and *they* are responsible
for behaving in a manner that doesn't offend other owners.
And in the governing board, all they see is a bunch of peers
acting like self-important ass holes rather than volunteers
who are burdened with the job of maintaining the property
and the living conditions for thankless people while keeping
everyone off each others' backs. As with parents, you don't

appreciate what members of governing boards have done
for you until you become one yourself.

>
> Technically, yes, but you are probably also aware that any
> contract that isn't a LEGAL action is NOT lawful, or binding.
> You can't enforce a contract that is not legal to begin with.

Read more slowly, and you may see what I have been
writing repeatedly (there is an example above) - that
UNLESS the CC&Rs contradict STATE or FEDERAL
laws, they prevail. That means CC&Rs are invalid if
they contradict those laws, such as prohibitions against
children. When our CC&Rs were written, they could
and did prohibit children residing for more than 30
days. Now such prohibitions are illegal due to a state
Supreme Court decision, and those sections of our
CC&Rs prohibiting children are no longer enforceable.

> [.......] I personally think that doors and windows to your
> privately owned "unit" are YOURS, they do NOT belong
> to the association.

By buying a unit in our Association, one commits
oneself to abide by the CC&Rs, and the description
of each "Unit" is clearly delineated in detail in a
condominium plan. It does not include anything
outside the inner surface of the walls or anything
outside the extension into the patio, by a specified
distance, imaginary planes formed by the walls
and ceiling of the adjacent living rooms. Everything
else is Common Area. And that is standard for
most CC&Rs, the major difference being whether
the patio is Common Area or part of the Unit.
Thus, when doors need patching or painting or
replacing, the Association does it because the

Association owns it - not the owner of the adjacent
Unit. Similarly for exterior window hardware.
That is how the Association maintains control over
the uniformity of appearance and how it avoids
having crazy owners painting or carving crazy
designs on their doors and windows that offend
the other owners and which eventually lead to
wars of festooning exterior surfaces that eventually
lead to destruction of each others' property. The
motto is this: "If you liked enough to buy it like it was,
you must like it enough to keep it that way." And
that's the only way to keep the peace.

> Walkways have never needed a railing, unless they are
> above ground level (2nd through xxx stories high) and
> are required for "safety" to prevent someone from falling.
> A walkway is simply a passage for walking.

Nonsense. Have you ever seen walkways at a
condo complex for the elderly? Ground level
walkways frequently have railings because of need.

> Main Entry: walkï¿½way
> Pronunciation: 'wok-"wA
> Function: noun
> : a passage for walking : WALK
>
> Note, there is NO REFERENCE to a railing.
> I've never known of a walkway to include a
> railing as part of the definition.

If you are arguing that a walkway needn't have a railing
to be defined as a walkway, OK, but neither I nor
anyone else claimed that a railing was a defining part
of a "walkway".

> Nor have I known the definition of Patio to have a fence.

>
> no reference to a fence here either. (courtyard however does
> reference being an "enclosure")

Right. The fence around a patio is part of the Common Area,
not part of the Unit or a part of the patio.

> My patio has never had a fence around it, and I don't know
> anyone else with a fence around their patio (unless their
> patio borders a pool, and they were required by law to have

> possible COVERED, but not "fenced". My patio is OPEN
> (not covered yet), so i can walk out into the yard anytime I
> want. My YARD is bordered by a wall though.

So what? Our patios are all fenced. The fence is 8 feet
high and built of tongue 'n groove boards so that no one
can see in. People like the privacy.

Yuri Blanarovich, K3BU wrote:
"Have you figured out how to model loading coil of particular inductance and physical size to reflect the real current drop across it?"

Current drop across a coil is E/Z where Z is complex. If a reflection is involved in the antenna, there are multiple Es involved, perhaps.

Growing or shrinking current through a coil, generates a voltage which opposes current in the coil. Because of its opposing direction it is called "counter emf". The change in current in the coil generates the counter emf. A steady d-c current in a coil generates no emf.

A given length of wire has much greater counter emf when coiled than when stretched out straight. We say it has more "inductance". It`s because fields from close-wound turns intercouple. With 3 turns closewound in a coil, 3 times the lines of force cut 3 turns, so 9 times the counter emf is generated. As a first approximation, the inductance varies as the square of the number of turns.

Opposition of counter emf in a coil delays the rise of current in a coil from the phase of an a-c voltage. In a perfect coil with no resistance, the delay is 90-degrees or 1/4-cycle. Resistance, useful or useless, reducees the current delay. Due only to the L/R ratio, the phase delay imposed by a coil can vary from 90-degrees down to zero.

I did a web search on "r.r.a.a" which produced 590 hits. One of these was something posted by Roy Lewallen entitled "Inductor Operation". Roy had measured phase delay in a loading coil. If I understood Roy, he found no phase delay in an antenna loading coil.

In my opinion, he should find delay even in a coil feeding a dummy load, especially if the coil is large as compared with the dummy load.

Best regards, Richard Harrison, KB5WZI

It's all a matter of interpretation. They do reserve that right. And if
you choose not to grant consent they can bar your entrance from said
establishment. The consumer then has the choice. Allow inspection or don't
enter.

No, they can't force your backpack open at the store threshold, but they can
make it a condition of being there.

BPL sucks.

Why use HF spectrum when there is so much other, more suitable and much wider, spectrum available way up the bands? Between improved DSL (higher speed, much farther, as being implemented in the UK), Cable, WildBlue (satellite), and soon Wi-Max (35km, 56Mbps), BPL will be nothing more than a footnote.

In the future, some of those HF users being bothered by BPL might stoop to doing a quick 'sweep' across the bands. This would cause the BPL DSP algorithms to think that all frequencies are in local use thus lock-out ALL the frequency bins and effectively shut down the link for several minutes.

BPL is a REALLY stupid concept. Obviously the HF signal is going to leak out (and other HF is going to leak in). Dumb. Power lines aren't exactly twisted pair (close, but no cigar).

BPL has about as much future as Fractal Antennas (none).

It might be profitable for you to actually try the measurement. Like
Roy, I also find no delay *across* a physically small coil. The coil
does cause a delay between current and voltage, and as theory would
indicate, that delay (and V/I phase relationship) appears everywhere in
the series circuit, rather than locally across the coil. But, as I
believe Reg and others have suggested previously, as the coil begins to
take on dimensions that are a larger faction of a wavelength,

propagation delays begin to produce additional effects, manifested in particular by the standing wave profile. In physically small, inductively large coils, I can find no propagation delay. This is consistent with the report on W8JI's web page. However I think it's reasonable to say that as the coil starts to become physically large, it begins to produce observable delays. These delays appear to be greater than one would expect for a straight conductor of the same length. Perhaps someone here can explain why that might be, but I am as yet unable to. I suspect that it's because as the coupling between turns is reduced, the coil begins to look less like an inductor, and more like a compact length of transmission line arranged in the shape of a helix.

73,

Jim AC6XG

My first post here in years and it's not about DSS systems. Arggggggg...

From the U.S. Government Training Manual, No. 2000-25 WAR DEPARTMENT,
Washington, November 30, 1928 and prepared under direction of the Chief of
Staff, under the title of "Citizenship":

"Democracy: A government of the masses, authority derived through mass
meetings or any other form of direct expression; results in mobocracy;
attitude toward property is communistic negating property rights; attitude
toward law is that the will of the majority shall regulate whether it is
based upon deliberation or governed by passion, prejudice, and impulse,
without restraint or regard to consequences; its result is dem-o-gogism,
license, agitation, discontent and anarchy."

Democracy = communistic attitude toward property negating property rights.

>Do you have any logical rebuttal to the bit about the BPL leaking out and
>ruining the HF spectrum (especially for SWLs, even more than Hams)?
><-ANSWER THIS.

My pleasure.

The FCC has, in it's changes announced yesterday, recognized that an occassional --bona fide-- RFI issue will arise. It has assumed that such cases will, in some circumstances, occur,and made it the onus of the BPL providers to provide for appropriate action and mitigation.

There is no evidence, nor reason to believe, that the low level of RF produced in BPL will propagate to bona fide interference levels, in the very or mid far-field.

That means that few active fixed-location radio amateurs will be affected in an adverse way: for example, most HF hams are inactive; and a vast majority of hams are VHF only these days. A simple sensitivity analysis suggests potential cases will be a few hundred in the worst, case, a few dozen in the best case.

You may hear BPL; the issue is whether it constitutes true interference. In a vast, vast majority of cases the answer is, and will be, 'no'.

Thus cases will be rare rather than common. Certainly less common than, say, TVI issues in the early years of television. (We all seem to forget that many predicted the downfall of ham radio when tv came into common usage.)

As for SWL'ing, I am not sure, given the redundancy of bands and the internet, that the broadcasts will be compromised. Is there evidence for this? Why is this important? For example: other than some indescribable indulgence, is it critical to hear Radio Tuva on the 30M band? Is the 40M band good enough ?

Would you be so kind as to ID? This screen you hide behind seems rather compromising, and unnecessary.

Jim Kelley wrote:
"The coil does cause a delay between current and voltage, and as theory would indicate that delay (and V/I phase relationswhip) appears everywhere in the series circuit."

As an example, place a perfect coil and a perfect resistor in a series combination. The voltage drop across the resistor is exactly in-phase with the current throuigh the resistor. It is independent of the phase of the circuit current. The voltage drop across the coil precedes the current through the coil by 90-degrees.

The phase of current in the series circuit with respect to the voltage applied to the circuit is determined with vector math.

>

Actually calling it an extant infrastructure is a gross oversimplification. They have to add signal boosters every couple of miles plus bypasses to every transformer. Where the lines are in the average condition for this country (which equates to poor condition), they will have to upgrade the lines themselves. Where there is noise on the lines, say due to industry (welders for example really put a lot of noise across them), they'll have to track it down and filter it out. Dry areas have a lot of static and they may have to shield the lines for reliable data transfer. The plains states have a lot of thunderstorms and once again they may have to shield the lines to have reliable performance.

There's a lot of expense in implementing this and a lot of time consuming work. The rural areas will never get it as there simply aren't enough customers per mile to break even. Besides by the time they get the rural areas covered, if they ever do, these people will have gone to satellite or WI-FI and there won't be a market.

> BPL will be one of many options many folks will have, and in many cases it

Not true. Small towns and larger already have dial up and many have DSL and cable access. Some already have WI-FI and satellite. People outside of the towns will NOT be served regardless of the marketing hype due to cost. Customers per mile won't justify it.

> Other options are bound to capture relevant market share as well. It's a
big

For BPL to capture and KEEP market share, it's going to have to be as cheap as dial up and as fast and reliable as cable or DSL. Otherwise it may get implemented in spots but is doomed to basically wither and die on the vine.

> That is why BPL is supported by both Presidential candidates. One of the few
> points both these gentlemen agree on.:-)
>

No they support it because of the marketing hype that has been done and the fact that neither is really conversant with the technology. After all they few it as having an infrastructure in place, which is in fact not true.

Obviously there will be market locations where the business case is compelling;
others where it will be not. Are you saying that they haven't done the business
case? I don't see evidence that your assertions come from such analyses.

The important point is that ham radio is not a factor in the business case, in my opinion. Ham radio: 'we did you already, didn't we?' Why should we belabor a point already dealt with, and deal with in great sensitivity and fairness?.

That is SO wrong. Senator Kerry--I know as a fact--is VERY cognizant in telecom matters, which include BPL. His staff is superb. I cannot speak from experience regarding President Bush, although I like what I hear.

After all they
>few it as having an infrastructure in place, which is in fact not true.

Sure it is. Infrastructure is not the same as implementation.

Hi Tony,

The true discone part only works above about 100 MHz. Occassionally these hybrid antennas have spikes of SWR from 100 MHz to 440, but I would say you should probably be fine--without tuner.

The "very best solution" would be to allow the utilities to use their extensive system of power poles to string a fiberoptic cable to residences (either direct, or maybe the last half-mile as an RF node). If the power companies had spent their lobbying and legal money on installing this base, a lot of people would now have high-speed net connections.

BPL is simply a poor technical solution, and is an interim communications step that should be bypassed. You may gloat over your prediction accuracy, but certainly not over the existence of any form of BPL.

> occur until a great distance from the antenna.

Now that explanation is worth a patent all by itself! If "radiation does not occur until a great distance from the antenna", just how does the energy sneak out that great distance and suddenly manifest itself? Don't know about your world, but I've been in the near field of a lot of antennas, and tissue heating easily proved that they were radiating.

I believe the quote is:

"You want physics?"
"I think I'm entitled..."
"You want physics?!"
"I want the truth!"
"You can't handle physics!"

Anyway, patents and glib text are cheap (well, maybe not patents), but far-field performance is the ultimate judge. Build me a couple of EH's, and compare them to dipoles, say, mountain-top to mountain-top. Get 3rd party witnessing, and publish. You know, extraordinary claims demand extraordinary proof.

> the clothes less the agreed-upon cleaning charge.

Exactly. As a small business owner, I too deal with that every day. We have what is commonly referred to as a 'mechanics lien" on any items we work on, and if the item is not claimed within a certain period of time, as determined by law, the item is by default OURS, and we can sell it for whatever we want, to recoup some expenses. I rarely ever do that, because there is not much reason to since i have space to store things and the customer typically comes back eventually. lol

> traversed by the walkway.

true. if there is a pond, or something else in an area that they don't want people trampling on, or falling into, they may put up a railing, or a fence, but a walkway in and of itself doesn't necessitate a railing.

That was my understanding here in the states as well. Same goes for them inspecting your bags/packages/etc. as you LEAVE a business. However, they have gotten around that by claiming they are doing it for YOUR benefit, to be sure they didn't forget to give you one of your items you paid for.

In todays world, i can understand them searching your bags if you are entering into a large public arena (sporting events, etc.), but it's still a little intrusive, and some people take it way too far. you'll notice that they don't physically touch your bag or anything when they inspect, they actually have YOU pull stuff out of the way,e tc., and they just glance in real quick, to be sure you aren't carrying anything you aren't supposed to. (this doesn't include airports, etc., where they do physically handle things regularly, but the average store, etc. that wants to check your bags won't touch them physically, at least not usually, and not here in the states).

LOL, You are trying to twist the facts. The fact is, a WALKWAY, by
definition does NOT include a railing, PERIOD. railings added for other
purposes, such as the elderly so they can hold on while moving around, do
NOT magically make them a requirement for a "walkway". Plain and simple!

Yes, you could argue that the fence around a patio in this case is part of the common area, because the patio doesn't reference a fence. I'd probably still challenge it, but this one might be a little tougher. It however would depend on the location with regards to the property owned by the tenant, etc..

>
> So what? Our patios are all fenced. The fence is 8 feet

You are just angry that I have proper definitions, that defy your own personal beliefs. the facts are, definitions hold true in most court cases, because these are the common reference points, and commonly accepted

definitions for such items, that MOST people would KNOW if they did a little research. Therefore, if the majority believe that the definition is as described in common reference material, it is FACT, and will usually support the argument. I would challenge your CC&R's any day of the week based on these simple facts. Tedium is what makes a WINNER. ;)

Ed, if my understanding is correct, the power companies will indeed be stringing fiber optic cables. There will be one going right by your house if you are blessed to live in an bpl blessed neighborhood. THe infrastructure must be built. I think there is an impression that the power companies are just going to alligator clip a bpl signal on the lines at the generating plant. Power lines are fair at delivering low

frequency and high power. At HF they aren't so hot.

So while you have the leaky, degraded signal with the dubious convenience of being placed from the HV lines to the other side of your line transformer (and let's just hope that has been worked out to be safe) wouldn't it just make more sense to get the fast signal from the proper source? Going right by your house....

BPL is the industry equivalent of putting bicycle tires on a top fuel dragster.

A triumph of politics over technology.

Then you agree that the French did learn something from their disaster in
Indochina. But not enough to avoid invading Egypt in 1956. Maybe the
post-grad course in Algeria was what turned them into peace-loving
post-colonialists.

Yes, the French have tried mightily to avoid foreign provocation. Why, take
Rwanda. As the genocide reached its peak in the early summer of 1994,
France's President Franï¿½ois Mitterand was reported to say, "In such
countries as this, genocide is not too important." IIRC, the French Foreign
Legion was really on a protracted African vacation in Zaire in 1978.

I cite these instances not to demean France (although I think the average
Frenchman deserves a better government than he usually gets), but to deflate
the Francophile pomposity you wear as a veneer over your hatred of America
in general and the present administration in particular.

Nothing I say will change your pickled attitude, so I'll grant you the
high-ground of a last idiotic reply.

See ? There's the bit your not getting.

I listen to SW. My neighbor signs-up for BPL. We share a pole-mounted transformer. The AC in MY house, under my desk, will be infested with BPL.

Eventually someone might drop by and install some ferrite onto my power line drop and that might reduce the noise by a few dB at certain frequencies.

The whole thing is a kludge.

By the way, there are plenty of reports of interference in other countries and in the US trials. Start with ARRL.org and read.

As a matter of fact, all open air portions of our
Units are called "balconies" in our CC&Rs,
whether they are on the ground or protruding
from elevated floors. But legal definitions would
just confuse you.

> You are just angry that I have proper definitions...

You have dictionary definitions of words in
everyday use - NOT legal definitions. As long
as our CC&Rs defined a "rumpus room", they
could call patios and balconies "rumpus rooms"
and be just as valid. In short, you are stuck on
everyday definitions and mistakingly apply them
to legal documents.

"Fractenna"
> ...what is the value of SW
> BCB in an era of web cast?

There ya go.

If you're willing to trade-off the HF spectrum against YAIP (yet another Internet Provider), and a sucky one at that, then BPL is a 'worthwhile' (sic) technology. We'll mark you down as firmly pro-BPL, anti-amateur radio, since you can spend your nights annoying people on the 'net rather than on the air.

If you don't understand the ultimate utility of the HF spectrum then <rolls eyes>... SWL includes a whole world more than just broadcasting. Your ignorance, or at least a very poor assumption, is showing. And BCB is the wrong acronym and the wrong band. Again, YIIS.

You've picked an argument and lost (badly).

Source record: 88419

Art has invoked my name so the genie comes forth to tell a (short) story
somewhat simplified:

A client invented a useful device. Application was made. A long time
passed. Application was rejected in a communication that contained only
English words, but that was unintelligible. Efforts were made for
clarification. "Clarifications" were unintelligible. Client fell on hard
times and could no longer pay more than court fees. Another patent attorney
and I filed an appeal a significant part of which consisted of quotations
from PTO communications. (As in engineering, when doing really serious
stuff one wants a second opinion.) A panel of three of the most senior
judges held in our favor with a chastisement (to us) for a non-traditional
presentment. Examiner appealed. Another three judge panel again held for
our side and ordered the patent to be issued. Patent was issued some five
or six years after the start of this process. Someday, the client might
pay, but is under no obligation to do so and we have the satisfaction of
having done the right thing.

I do not think that things like this happened in the PTO in the "old"
days. All of those examiners could read and write in the English language.
Many, perhaps most, saw their time in the PTO as part of an apprenticeship
not as a job.

As an aside: I admonish you not to believe the characterizations you
see on TV.

Discone lower frequency cutoff is near the length of the skirt (1/4
wavelength) so measure it 100 Mhz is about 2.5 feet, 28 would be 9 foot.
Impeadance is great over the range, should not need tuner, unless the
discone is built cheap. I have a Mil one, good from near 200 to about 1.2
Ghz high power. It has 12 rods that make up the skirt. Google it to check.
UHF should be great.

>tuner if I would, let's say, try to operate on 2/6 or 440?

Hi OM,

The need for a tuner, and the justification for the use of an antenna design are separate issues. A dummy load will always tune up....

As for this frequency spread, yes, the Discone could easily tune up on these frequencies, and every one in between. You also need to consider what will happen if you actually try to USE this antenna for a purpose other than a dummy load.

For one or two octaves it may operate very usefully, but when you try to stretch it over a decade of frequency you will find that its best performance is straight up for occasional satellite work.

When you get into the high end of the "specified" range, the overall dimension of antenna becomes end-fire straight up because it is becoming significantly long in terms of wavelength. If your interest is in activity along the horizon, then you would experience a sensation of being "deaf."

This deafness is the most common complaint of mis-interpreting the ability to tune with ability to use.

wrote:

|(1200 new registered voters in 3 days)

If these folks haven't bothered to register before and educate
themselves on the issues, why should they be voting?

As a BTW, the citizens of Arizona have the right to initiate law via
the ballot. (There are a couple of propositions on the ballot to take
away this right, politicians not wanting any meddling by the common
folk, doncha ya know.)

One of these initiative propositions would require a simple proof of
citizenship when you register and when you show up at the polls. The
usual suspects, i.e., the newspapers, the Hispanic "activists", my
gerrymandered-into-office Hispanic congressman, etc. are needless to
say suffering from severe panty bunching over this.

They claim that there has never been any instance of non-citizens, or
those ineligible, registering or voting.

The evening news just reported that 45 residents of the county
lock-up, felons all, were just registered to vote. Some of them
several times.

I guess that's good, huh?

Perhaps He WANTS to listen to the short wave bands! Who really gives a crap about web cast, if he chooses to listen to the radio? I hate to break this to you, but the world does not revolve around the bloody internet!

Ok... the day is under arrest...Should I hold it for 72 hours?

>Solve a pressing problem.

BPL is a dumbass answer to a nonexistant problem.

>BPL looks very promising.

It would, to you....
Simply put....BPL, in it proposed configuration, sucks. Only
tweezerbrained people with a commercial or political agenda would
disagree. The idea of the HF spectrum becoming a digital noise
wasteland does not appeal to me. I bet the people over at Houston
Universal Radio will just love it. I can hear it now...Continental
1256 heavy, you are 1 by 1....You are buried in our BPL garbage bin.
Call San Juan Radio... Maybe they can hear you....Forget New York
Radio, they are in worse shape than we are. If no joy, just deviate to
Boston, descend to 2000 and stick your head out the window and yell
real, real, real, loud....Maybe that goofy ass Chip will hear you and
will relay your intentions back to us via his coveted BPL internet
connection....Then, again, maybe he won't...MK

Hello All,

One of the things you learn in a classic "liberal" education is that oftentimes reality mimics fiction (and even more frequently, much to the consternation of fiction writers, if you attempt to write actual events it comes out sounding wholly absurd). This has just occurred in conjunction with the purple prose offered above compared to the reports of recent events from the Insurance Industry Debacle:

"Shares of Marsh fell another 16 percent yesterday, to close at $29.20 after plunging on Thursday. In the last two days, the stock has fallen 37 percent, wiping out about $8 billion in market value."

The current ethic (or should I say the emulation of the Republican perversion of government for sale) has robbed the investor of $8 billion (should we privatize Social Security to add commissions and fees for this transaction?).

One time loss.... Will never be repeated..... Isolated event.... Hiccup in the statistics..... Market aberration.....

"Shares of A.I.G. also fell sharply a second day, closing down 3.6 percent, at $57.85, a loss of $24 billion in market value over the last two days."

If we do the math, more money has gone down the tubes in 2 days than will be spent in Iraq in 6 months. Who's the terrorist organization? Do we go after Ossama, or do the American thing supporting the Corporate welfare state and take out that trial lawyer Attorney General Spitzer?

That can be a bit more difficult, at least in the US. The sign
would have to be very well placed, and even then it might not fly. An
exception would apply to membership stores where you agree in writing
that, as a condition of mambership, you agree to inspection (of cart
contents, anyway) upon exit. They've recently started posting large
signs saying it's for your *cough* protection *cough*, like to make
sure any applicable rebate information was printed on your receipt.

It's become pretty much of a game at an electronics chain
called Fry's, which everyone likes to mock. Some of their door guards
get pretty testy at times, though most know that they're not to push
it when a customer blows off their attempts to "inspect"

For some low grade entertainment, google frys + electronics.
The horror stories can be quite amusing.

>If you don't understand the ultimate utility of the HF spectrum then <rolls
>eyes>... SWL includes a whole world more than just broadcasting. Your
>ignorance, or at least a very poor assumption, is showing. And BCB...

Thanks for your opinion.

Firsty, I am not the FCC. This issue was duly considered and carefully thought through, so please don't use me as a proxy: they know more about the SW BCB than me.

Second, I asked you to educate me: not because I'm clueless, but because I wanted to give you the benefit of perhaps mentioning an aspect of this, that is (allegedly) beyond the extant solutions and prescribed remedies of Part 15.

If you think its worthwhile then its worthwhile to you: I'm glad you enjoy it. The issues are:1) what is preventing you from getting the info in the multitude of ways available; 2) what steps have you taken to mitigate the interference (if it exists); 3) can you cite cases where --bona fide- broadcasts to North America were uncopyable from all locations (with extant filtering methods) of a residence because of BPL ?

As for non- BC SWL'ing, may we presume that the intended transmissions were not made for your information nor benefit? If so, then how is one to presume that eavesdropping from a residence as a form of entertainment needs to be assured under all times and conditions?

It would be unfortunate to presume this is my argument: remedies have already been prescribed due to these arguments being prevuiously made to the FCC. So, why aren't they sufficient?

Please: some substance. Let's learn together--no malice intended nor sought.

Hi Brian,

I imagine that when 10M comes back, I will be fascinated to do so. I still have the JRC and use it for MF antenna testing on occassion.

I do hope that, when this occurs, we in the ham 'fraternity' (a horrible sexist misnomer IMO) will have finally switched to voice-digital modes on HF and away from SSB . Such digital modes are far less sensitive to supposed 'interference'. About time we were 'with it' and don't let the totality of the wireless/telecom revolution pass us by..

> Maxwell, W2DU

Firstly, sorry for the 'e' in 'fraud' which does not belong there. In fact, I asked for help from the hams' fraternity ('all the people know all' ) - and in connection with the US PTO patent No. 6,486,846 B1, issued on November 26, 2002 to Robert T. Hart. I live on the fifth floor of a condominium building, and like many hams, I have no space on the roof for a proper antenna. So, an EH-antenna would be ideal - if it worked. I have not tried to build it yet, but I am trying to learn about it as much as possible before that.

Obviously, my question has two aspects: a practical and a theoretical one. The practical one: "The proof of a pie is in eating it." Has anyone built it and can testify it is successful at least as much as a standard dipole - according to the inventor's statements? I have not found such an answer yet.

The theoretical one: My theoretical education in that field is rather amateurish, but still I think I can put some questions: On the EH-antenna homepage (http://EH-antenna.com) I found a statement that in the classical dipole the E and the H fields are a result of a LINEAR movement of electric charges, while those fields in the EH-antenna are a result of the ROTATION of those charges - a feature unknown until now. Nowhere in textbooks could I find any word about this possible phenomenon. In science discoveries must be double confirmed at least, but here this is not the case.

By the way, it was interesting to read that once an issued US Patent was a guarantee that the patent at least worked, but today it seems it is only a certificate that someone was the first to register his idea or wouldbe invention. If so, I could even understand that, because today the USPTO should have armies of different experts and endless laboratories to test all the applications. However, it would be fair to openly proclaim such a principle. In my country (Croatia) the situation is similar. (The other day I read in the newspapers that someone got a patent for superconductivity at normal temperatures (through some alloys), although, to my knowledge, nobody saw it work.) Imagine a coil without ohmic resistance, or long distance lines without any losses!

I am still dreaming about an ideal antenna having not more than 10% of wavelength and 100% efficiency. Thanks for all the posts, anyhow.

Bozidar, 9a2hl

>Bozidar, 9a2

Moderate/high efficiency with a 10% physical height is pretty easy to attain.
That's not an e/h antenna, as far as I am aware.

The e/h antenna appears to ignore the main point about Maxwell's equations:
changing fields generate changing fields. E' make B's and so on. You can't
separate a changing E field from its B field, and so on. Thus the premise is
wrong.

In a --very-- small volume (fraction of a radiansphere), any single current max
radiator is very inefficient. Similarly, any multiple current max radiator does
not exhibit constructive interference in the far field. That's the physics.
Antennas as a pure science are now an exhausted field.

My understanding is that there is also a problem at the other frequency end.
For example, if it actually works on 6 meters, then, at 432 MHz you will
have very high angle radiation; i.e. going up, instead of along the horizon.

This is what "Freedumb loving people" want!

Lost, is the notion that a constitutional republic once offered the greatest protection of individual and property rights while encouraging economic growth under free enterprise. We appear destined to follow the Ur-a-Peon model of high-density housing voters electing our rulers. Subjects v. citizens, for the common good, isn't that sweet. We can gather in our collective-gardens and listen to National Public Radio whilst our selected rulers redistibute the last "earned" wealth remaining...to themselves. Before that time Idaho will have closed its borders.

Jack

You're one of those brainwashed, Orwellian-fans.

You're living down to your well-established reputation as an idiot.

It is apparent that you'll not be convinced, so it is a waste of perfectly good bits to argue further.

Oh, you ask me to cite references, I did.

You big fat jerk.

My dear friend,

This is not a personal issue; I have faith that you can transcend your tone here and say something that could be helpful in making your point compelling.

If the point is compelling, then it certainly would make your case , which would undoubtedly be carefully echoed in the BPL issue.

Emotional gut reactions and name calling aren't the way to convince those who make the decisions.

I tried; I am sorry I cannot help you unless you help yourself.

Best wishes,
Chip N1IR

>
>Tam/WB2TT

Hi Tam,

If its the design I've worked with, it should be OK on the horizon on 432.

When the disc section no longer functions as a counterpoise, then multiple resonances happen across the cone and you get a lobe on the horizon. That is probably what you are describing.

From: - XC - <nobody@home.net>
Message-ID: <gfqdnc9KB4pyruzcRVn-oA@comcast.com>
Source record: 88345

Hi Old Ed, it's pretty easy, just did it myself, you just need to setup a message rule.....

-Go to menu Tools/Message Rules/News
-On the New News Rule checkoff in the following boxes to setup a new rule:
-1) Where the From line contains people
-2) Delete it
-3) click the Contains People link

-type in the name of the offending sender, then Add, then OK
-couple more OK's to close all the windows and put the settings into effect
(you can repeat the above to add more names too)

Have fun, you can add, modify, delete as many rules as you like.
The next time you access the group you will not see any *new* posts from that person.

73,
John

Because the "extant solutions" will not work in the real world.

Why, we could save a lot of money and trouble if the product emission requirements of Part 15 were eliminated. Then, the general population could deal with interference problems on a "case-by-case" basis; if you were experiencing an interference problem, all you would have to do is locate the source and invoke the general "shall not cause degradation to licensed services" clause, and the offending source would be quickly technically fixed or permanently shut down.

Anybody who thinks this is practical must have a mental age of about 7 (and pardon me if I'm insulting 7-year-olds).

Source record: 88349

Hrm...

Anyone else see the callsign in my post? Fracky here doesn't see it.
(It's blatantly obvious if you know where to look.)

Yes, I drive truck, by choice. I own two of them, as a matter of fact.
I paid taxes on over $150K last year. I'm a successful independent
business man. How'd you do last year?

Prior to that, I was a regional tech support manager for Bay Networks.
I was making a 6-figure salary there, too. Got burned out and decided
to do something a bit less stressful. It works for me.

Prior to that I taught electronics at a trade school in Salt Lake
City, UT.

Prior to that I was enlisted in the USMC, where I was a networking
technician, small computer systems technician, and was stationed with
1st MarDiv G-6 on mainside, MCB Camp Pendelton, and 11th Marines on
Las Pulgas, Camp Pendelton.

Who's your friend, anyway? Doug, N8WWM? George, WA3MOJ? Known trolls
in rec.radio.cb.

CB is required for my job, so there's that. I also have HF and VHF
gear in the truck, and am licensed to use it all.

Since when is someone's choice of employment indicative of their
intelligence or abilities in other fields? Look up the definition of
Amateur in the dictionary, Fracky.

As for your implied insult, sugar-coated as it was, it didn't hit
home. Try again, Trollboi.

And if you'd ever care to supply that performance data that I asked
for oh, so many years ago, I'd still be interested in seeing it. I'd
like gain figures, and directivity figures of your 10M fractal against
a balun fed 10M dipole oriented in the same direction at the same
height above ground, on the same frequency.

Tom Donaly, KA6RUH wrote:
"Richard, there is no such thing as a "current drop."

This is where i came in almost a year ago. Yuri may havr posted Fig 9-22 from page 9-15 of the 1994 edition of ON4UN`s "Low-Band DXing". There are base loading, center loading, and continuous loading examples of short vertical antennas, and their current distributions. In every case, the currents at the two ends of the coil are different.

The impedance of an antenna is a function of position along the antenna. There is radiation from an antenna so not only is the impedance along an antenna a variable, but the the transmit power level power level along an antenna is a variable, too. These variables ensure a difference between the current into and out of a loading coil.

Current is high where impedance is low, and current is high where power is high.

Best regards, Richard Harrison, KB5WZI

That's not going to happen any time soon. No time, and no desire to
get within 100 yards of you. At least not until you can show you're
man enough to provide the data I requested on your fractal antennae.
Even then, I'm not sure I want that much to do with you.

> 73,
> Chip N1IR

Oh, and I am licensed. In fact I went from 22 years on just CB to Extra in 6 months, without having to study anything except the Code. I'm dyslexic, so I had quite the time with that. Took me three tries to pass the code, but I did it, without a waiver.

So just take the "you're not smart enough to have an intelligent conversation about antennas" attitude and point it elsewhere.

wrote:

>If these folks haven't bothered to register before and educate
>themselves on the issues, why should they be voting?

Hi Wes,

The HAVE. The problem is we've had a spate of "volunteer" groups
who've pre-screened some registrants and those forms NEVER making it
into the office. Another problem is that we have had a FLOOD of new
registrants this summer (100,000+) in this county, and that has choked
the system such that when they go to check their status, their form
may have not cleared the bottleneck, and the office suggests if there
is any doubt they should apply again. At our first stop, quite a few
have been Troops and the families of Troops and I suppose they've been
too busy out of country (or on their way) to read the paper. The
problem of getting Absentee Ballots has been widely reported in the
Army Times (they had offered solutions last summer, Congress has had
problems fulfilling those solutions for some reason).

To All,

Anyway, it is now national law that any registered voter must be given
a ballot even if their name does not appear on the Voter's Roll.

If any of you is denied a ballot because they claim you do not appear
on the Roll, they cannot deny you a "Provisional Ballot" (this name
may vary by state). If they stonewall you claiming they "never" heard
of such a thing, then you simply go to another Polling Station and
make the same demand (you do not have to be at "your" Polling Station
to vote this way). If your state varies from this significantly, then
you should move out of Florida. When you vote "Provisional Ballot" be
prepared to have it placed into a security envelope, where you will
provide your name, signature, place of residence such that when your
name does appear on the Roll that it can be reconciled and the vote
tallied.

In a wartime situation, the internet may, and probably will, be down.
The knowledge and expertise of people who can both receive and
transmit on HF will be invaluable in such situations.

If BPL is trashing the bands, it will make it that much more difficult
to receive HF broadcasts, and HF Amateur transmissions, which will
tend to get people away from HF. They won't want to put up with the
interference. Bad idea.

Two element 10M FQY= 4dBd compared to such a dipole; F/B about 20 dB at that gain. Last version had bandwidth of 1.5 MHz for 2:1 SWR.

You can see a professional 3 el version for a higher frequency on the slideshow gif on www.fractenna.com.

From what I've seen, about 50 science fairs have had these quads over the years. Always happy to help those who are polite and have legitimate interests, such as students.

Chris, when someone pays you a compliment, don't take it as an insult to your intelligence. Truck driving is AOK with me; I have relatives out your way who drive trucks.

So, when are we goin' fishin'?

With the caveat that I think the FCC is about the most open example of our Federal government, I have to point out that "due consideration" is a real hoot. Oh sure, issues move along in their majestic dance through the FCC's bureaucracy, but, after all the technical discussion has been input, there's a big, heavy political thumb on the scales of justice. Every FCC Commissioner is a political appointee, and they are all professional administrators, without a trace of experience in electromagnetics or communications theory. Each Commissioner has his own philosophy that he tries to bend the FCC toward, with top-down influence and an eye toward his next career step. To think that hot-button political issues (internet access for everyone) and special interests (what politician doesn't need money, if only to periodically fund his re-election) don't guide the technical issues is to be willfully naive.

Shocking as this may be, Fractenna (and my dog) just might know more about some aspects of electromagnetics than one or more of the FCC Commissioners. OTOH, FCC Commissioners have more friends, dress better, get more sex, and are far more wealthy and articulate than either.

Mr. Powell is one bright guy, IMO. He, an attorney, has dozens of engineers and scientists at his call, some of the very best in the country one may presume. He has great respect for radio amateurs and our issues, also my opinion.

You are right that he dresses better than me, at least for daily fare.

I think he knows what he's doing.

CB is intended for short range communications, under 120 miles. Rarely will a legal station be able to transmit much more than 20 miles, when the hash and trash aren't throwing their deadkeys and noise toys. Completely different subject.

Chip, you probably haven't been out driving around in the areas they were testing BPL, while trying to work a net. You can hear, literally, the "motorboating" from BPL interference 40-50 miles away from a test area. By the time you're within 10 miles of a test area, the noise from the BPL (different from magnesium lights and other urban noise sources) is close to 20db over S9.. making working the net nigh-on impossible. We're talking, minimum, a 100 mile radius around a BPL test site where the interference from BPL makes Amateur HF communications, at a minimum, extremely difficult, and at worst, impossible.

Now, mind you, this is receiving from a "compromise" antenna. I've tried switching types from my 40-foot, ICOM AH-4, tuned looped longwire, to Hustler "dummy loads", to Hamstick whips, to Iron Horse whips, to 102" SS whips tuned with LDG tuners, on the 10, 20, 40, 75, and 80 meter bands. ALL of them were affected to varying degrees, but none were affected so little as to make communications in these areas possible.

So your contextual assumptions do not apply to this situation in the least. IMHO, BPL is a bad for the Amateur community, and for emergency communications in general.

The interference on CB is a completely different story.

Ham Radio magazine published a number of articles on the design &
construction of antenna masts for ham applications.

http://webhome.idirect.com/~griffith/hr/hrind01e.htm

The ARRL store sells a CD for $40 which contains all issues of HR
magazine and then some.

Let me repeat, for those who might be tempted to use the term "current drop" in their casual conversation, there is no such thing as a "current drop." There can be variations in current in transmission lines, antennas, etc., but those are not "current drops." I'm surprised at you and Yuri, Richard. You two will have the CBers laughing at us.

Aside from all the legal arguing and BS within this group, the 5 gal can with concrete is a time proven method if the dish is adequately shielded from the wind. I have attached to similar railing using large stainless steel hose clamps. You can open the hose clamp, slide on a length of heatshrink tubing or even plastic hose and that will usually protect the railing surface. The hose clamps can hold a chunk of wood or fabricated metal to attach to the dish mount.
Good luck and happy TV.

I agree that the power companies can't couple to their intermediate distribution lines, since coupling across the next set of step-down transformers is poor. I was thinking that the power companies will have to run fiberoptic to the customer side of each of their lowest-level distribution transformers. (As an example, in my case, my residential power feed is a 240 VAC line that is parallel shared with about a dozen other residences. This 240 VAC is created from a 16 kV to 240 V transformer.)

The power service is already "right to my home." OTOH, the 16 kV distribution feeds are not always "running right past your home." (True, the 16 kV lines do run past some homes, in order to get to an efficient feed point for the 16 kV to 240 V transformer. Some people have their power flow "past" them, at 16 kV, only to come "back" at them at 240 V.)

BPL, as I understand it, will be radiating from a huge number of these 240 V residential clusters. Since the power company will have to use fiberoptic to get to their step-down transformers, it seems like they should use fiberoptic for the last leg too. (And then they wouldn't need a fiberoptic-to-240 V coupler at the transformer nor the 240 V-to-coax coupler at each residence.)

Understood that you have certain feelings on the matter. Nonetheless, after careful analysis of the data, the FCC does not have the same extreme view. It is time to move on,not waste any more time and money, and welcome the new technology. Provisions exist to deal with the rare problems when they come up.

I would be very interested in any recording you may have of noise levels that high, Chris. Certainly you have greater mobility capability than many others in noting potential RFI from tens of miles away.

>
Unfortunately those diagrams are misleading. They draw a current profile against a scale of electrical height, which makes it look as if there is a significant change in current along the length of the coil.

The current profile can only be correctly drawn against a scale of *physical* height. Then the error goes away, and the current is seen to be uniform through the coil. What does change is the shape of the current distribution above and below the coil.

All of ON4UN's math is good, and if you follow that instead of the pictures, you will find that the current through the coil is always assumed to be constant. In other words, he assumes an ideal inductor. The text and math shown that ON4UN actually understands the situation perfectly. I don't believe for a moment that he expected those diagrams to be so fundamentally misinterpreted.

>The impedance of an antenna is a function of position along the antenna.
>There is radiation from an antenna so not only is the impedance along an
>antenna a variable, but the the transmit power level power level along
>an antenna is a variable, too. These variables ensure a difference
>between the current into and out of a loading coil.
>
No: there is no change in current through a coil that is physically tiny, and doesn't have any capacitive coupling with the rest of the antenna. All the changes occur above and below the coil.

Any deviation from equal currents in and out has to be caused by the physical size of any real coil being non-zero. Then, even a physically small coil will behave like a very short section of helical monopole antenna. It is radiating an EM field, so there must also be some variation in current along its length. (The extreme case of a long coil is the fully helical whip, where the antenna and the coil are one and the same.)

There is also a lot of loose talk about "phase variation" due to an ideal inductor. This is NOT a phase variation in the current from end to

end! What changes is the phase of the voltage between the input and the output. At each end you are measuring the phase of the voltage, *relative* to the phase of the current which does *not* change.

Now someone is going to come right back at me, talking about "real life" this and "practical" that. But if someone does not understand how an inductor is even *meant* to behave, all their practical knowledge is built on sand - they may know lots of stuff, but they don't truly understand it.

Congrats on the persistence!

Back when I took the extra, you had to send 20 WPM --with a straight key--unless you were rich enough to have and bring a keyer--they weren't small or built-in those days! I think I could still send 20 WPM on a straight key, but I'm sure my arm would cramp up real fast.

The first time I took the general, I failed on the code copy. I bought one of those code LP's (I'm old, I know) and then studied a little. Failed again. That very night, I sat copying W1AW and did so for 30 nights straight.

Then I passed the exam.

Good life lesson for a youngster.

Just as I would be interested in the sources of your data on the
Fractal antenna vs. the dipole in the aforementioned situation. That
is to say, the name(s) of the test range(s) you employed, and a POC at
each range.

Until that happens, my data is just as valid as yours. Of course,
mine's reproducible, and I can cite many others who have experienced
the same interference from BPL on different antennae than I've tried,
to include bugcatchers and screwdrivers.

I have a feeling my data is more valid than yours.

Besides, you try to document S-meter readings on different HF rigs
while rolling 65+ MPH down the road in a 73-foot long articulated
vehicle weighing up to 80,000 pounds. I'm sure you'd rather have me
driving than writing.

I can only document, after the fact, where, when, and a very close
estimation of what the s-meter readings were.

Can you even come close to this?

I'm young.. but I'm not that young.. I remember 8-tracks, and they
were still popular while I was a child. I still have LP's, and a
player that works to play them on. Besides, Vinyl Sounds Better.

I got into Amateur radio later in life. In fact, I've not yet been
licensed for 4 years. This still doesn't speak to my knowledge in this
area.

I'll be the first to admit I have things to learn, and I'm no expert
in any one area. I do know what I've experienced with BPL, and it's
not been pleasant. Just ask the folks around the Orlando, Florida
area... Their BPL tests can be heard all the way across the state in
Titusville, and so greatly that it interferes with communications.

## 581. Re: Patents

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-16 19:08:13 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <ckrrit$n7e$1@hercules.btinternet.com>
Source record: 88276

There is an antenna with dimensions as small as 1 / 70th ( 1.43 percent) of a wavelength which has a radiating efficiency as high as 98.0 percent.

It is a vertical copper tube, 1 metre high (39.4 inches), 25.4 mm (1 inch) in diameter, operating at 7 MHz.

It is only 0.86 dB worse than absolute perfection, equivalent to a loss of only 1 / 70th of an S-unit.

It is more efficient than a very high half-wave resonant dipole, using 14 awg wire, at the same frequency. And uses a far smaller amount of expensive copper.

Has anybody ever applied for a patent for such an antenna which has such an outstanding performance? And did the Patent Examiner raise his eyebrows at the claim?

I have an unanswered question about BPL. Where I live has a very old power line system, full of splices and corrosion. How will splices affect the 1) the internet signal and 2) RFI?

Randy ka4nma

I don't know of any patents, but these "wonder antennas" are so
"efficient" because they use the feedline as a radiator. The feedline
is just terminated with a huge capacity. There is no magic to this -
it is just bad engineering. Good morning RFI!

Kind regards, Eike

# 586. Current in loading coil, EZNEC - helix

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-16 20:59:10 UTC
From: k3bu@aol.comNoUsama
Message-ID: <20041016165910.16808.00001863@mb-m11.aol.com>
Source record: 88281

Howdy Antenna NGers,

I took the time to check out the Helix feature in EZNEC 4.08 and modeled the "worst" case - CB whip or 10 m whip with loading coil - helix half way up and then the same helix moved up to 3/4 way up. Things will get more pronounced when more turn, more inductance coil is used and frequencies are lower. Yes, Virginia there is a CURRENT DROP across the loading coil, unless you have more "appropriate" or "scientwific" term for it.

Rough dimensions: 1m mast (5 mm copper wire/tubing), 20 cm long coil/helix with 5 cm diameter turns, 5mm wire diameter, 10 turns, spacing 2 cm followed by 1 m whip
Resonated at 27.05 MHz
With base current 1 A, at the end of mast/start of coil the current is 0.87457 A
at the end of coil/start of whip the current is 0.66884 A - a decent drop of 0.20573 A or 20.5 % - not an "EQUAL" (you DC coil believer types!!!)

Then I moved the same coil up 50 cm, so the mast was 1.5 m, same coil, followed by .5 m of whip.
Again with base current of 1 A, the bottom of the coil had current this time was 0.65479 A, while top of the coil 0.37127 with larger drop of 0.28352 A or 28.3 % - even bigger not "EQUAL" with resonant frequency moving up to 28.7 MHz, which corresponds to REALITY measured, experienced and finally properly (close enough) modeled. Even M0RON (with apologies if there is call like that issued :-) can see the nice current drop across the coil displayed in the VIEW.

Thank you Roy (now you believe it?), Cecil, Richard. Now the unbelievers can even model this case themselves and SEE it properly. So ON4UN, K3BU, W9UCW, W5DXP, KB5WZI were and are right. W8JI, G3SEK et al are sooooo wrong :-) Some still persist, some are converted and many will be enlightened.

Now if Roy can incorporate elegant way of modeling real life coil/inductance by inputing Inductance L and its physical size and have it calculate things without modeling turns, that would be a winner and a segment saver.

So after all, those "dumb" hams pointed out 50 years of misinformation in even ARRL "bibles" like Antenna and Handbooks :-(yep, latest 2005 "revision" still has it in it)

Just watch W8JI to massage his web page and twist out of this one (yet another egg in the face :-)

Good point ed !

Here in NC the bpl was wifi with a sealth antenna inside a streelight
so the hoa and others would not see it.

I agree, with all the poles they own along with the hi tension right of ways,
would cost them less to bury the fiber on the way then go wifi.

Sorry but I don't think so !

No, I don't have an impressive resume or advance degree in RF or anything.

BPL can't turn a profit without a large customer base. So, this bs about
the rural folk getting their internet cheap don't fly because of all the
hardware they need to string out in the country and that cost money.

Do you think the telco and cable co will loose customers to bpl, I don't.

DSL has dropped in price several times since the BPL dog and pony show
has started. Cable roadrunner has reduced the price and increased speed.

Now cell phone companies have the capacity to offer it via the new phones
and with a network card in your laptop or desktop.

If people need internet in rural area, let them dial in like I do.
Sure the kids need internet to stay on top of stuff but don't need
to download Gb size files with music and movie crap.

The internet signal will be crappy and subject to interruption by static from all kinds of sources. RFI generation will be severe. I do not know whether the splices and corrosion will make it worse but it certainly won't help matters.

>Where have you been Ian? Applying DC current behaviour in the inductor to
>standing wave RF current situation in the antenna, Eh?
>
No.

Step 1: I am starting from the fundamental AC current behaviour of an ideal inductor. The phases of the voltages at its opposite ends are different; but at every given instant, the currents at its opposite ends are equal and in phase.

2. I am expecting that ideal inductor to behave in exactly the same way when used as a loading device in an antenna - which in fact it does, because exactly the same laws of physics apply.

3. Then I'm in a good place to start to think how that behaviour will change for a real inductor that has both physical size and capacitive coupling to the rest of the antenna.

>In case you missed previous exchanges
>http://www.k3bu.us/loadingcoils.htm
>
>That is in practice and (right) theory. Cecil showed (hairpinned) model in
>EZNEC. And that ain't no lie!
>
>73 and keep your readers informed properly :-)
>

Oh, I shall, I shall...

I'll begin by pointing out the obvious: an ideal inductor, a honkin' great length of Airdux and a shorted parallel stub are three physically different objects. Each one is a different kind of loading device, with different effects when inserted into an antenna - and none of those loading devices is the same as the length of real antenna that it's claimed to "replace".

The flaw in your viewpoint is that you are expecting a loading device to "replace" too many of the properties of a genuine piece of antenna. It actually replaces very few of them, and each different loading device does it in a different way.

Cecil's stub behaves exactly as expected - for a stub. But a shorted transmission line is not an inductor - it has some of the properties of an inductor, but not all of them. In particular, the currents at its two terminals can be unequal, because a stub can carry common-mode current and radiate and EM field, which an inductor cannot. Therefore the stub example is irrelevant to a discussion that is trying to compare various inductors.

The same is true of different types of inductors. The ideal inductor and the Airdux are both loading devices - they do not completely replace the missing piece of the antenna. They replace it in one respect only (making the feedpoint reactance equal to zero) but all other things about the loaded antenna are *different* from the full-sized antenna. In particular, the current and voltage distributions above and below the load are different from full size, and so of course is the feedpoint resistance.

I cannot explain every detail of Barry Boothe's measurements, but I know for certain that the true explanation is the one that obeys all the laws of physics and circuit theory, down to the last detail.

What you have, Yuri, is an "explanation" that uses those laws in some parts, but twists or ignores them in others. That cannot possibly be correct.

>
>73,
>Chip N1IR

As I understand the theory behind Hart's 'EH' antenna, he believes that if the E and H fields in the radiator are somehow caused to be out of phase the radiation will be greater. We all know that when an RF voltage is applied to a conductor, such as a single-wire antenna (the radiator), a corresponding current flows in the radiator. We also know that the current flow produces both electric and magnetic fields, and the crucial point in this is that the E and H fields are inherently IN PHASE in time, but in space quadrature (90ï¿½ apart). Physical laws of nature as determined by Faraday and Ampere, and finalized by JC Maxwell, show that the E and H fields are immutably etched in time phase, and nothing in the feed configuration can alter that relationship.

Now along comes Hart, who says he can alter that relationship by inserting an inductance in series with the radiator, which he says delays the current 90ï¿½ behind the voltage, and thus the H field is delayed 90ï¿½ behind the E field.

I haven't read the claims in his patent, only the fiction appearing on his web page, but if the claims reflect his misguided, and invalid theory about altering the relationship between the E and H fields propagating along a radiating element, the US Patent Office has established a new theory of electromagnetics that contradicts Faraday, Ampere, and JC Maxwell.

What are we to do? Somehow we must fire the SOB's at the PTO.

Walt, W2DU

PS--don't you find it ironic that when radiation measurements are taken in the far field the measured power already relates directly to the power delivered to the radiator? Then if Hart's version radiates more power than the standard radiator, where does his extra power come from. Looks like he's invented a new version of the perpetual motion machine. After all, it's patented, isn't it? So it's gotta' work.

If open wire (telephone line) is a precident- ANY HI RESISTANCE, or ground, or
arcing in the instance of power will cause an unbalance of the circuit. This causes
a very high noise level on that circuit pair,
and would also cause it to RADIATE interference! And,
consider, that power companies have substancial arcing (caused by dirt, and loose
hardware), and ESCAPE (the induction from an A.C. line to other objects, if the
voltage is high enough and the magnetic field is strong enough), like fence lines
and telephone co. messenger (the steel cable that supports their telco cables),
paralleling it, and arcing to ground - there are several undesired effects even
WITHOUT BPL to cause QRN ! And btw, it is NOT necessary for a very good ground
to cause problems- just tree limbs are enough to cause a problem in this area.
ONLY GOOD part of the situation is the more current that flows thru the wire
(and hence the sleeves), the internal arcing in those bad sleeves tends to "SEAL"
or heal themselves for a duration- but if the current lowers to a substantial
amount, the problem will be BAAAAAACCCK !!! As info, Jim NN7K

That's nothing, have you seen : "Antenna faster than light?"

Saddly, patent laws were screwed up few years back, looks like patent office is rubber stamping applications as they come.

Then there is a bunch of "ham extremists" trying to apply DC laws to loading coils, ingnoring reality, parroting what they learned in the DC class. Good thing itsa ju's a hobby.

You can't explain reality, but you have good arguments to support your
"theory".
Now you can plug in solenoid/helix into EZNEC 4.08 and see for yourself
what'sup (See my other recent post). We are not claiming that hairpin is exact
replacement for lumped inductor, but some properties when inserted into
modeling program illustrate better what is really happening (current is NOT
equal at both ends of the coil).
Take the fricken RF ammeters and stick'em in the coil's ends, you have
excellent current probe on your web site. As you can see from W9UCW
measurements and my recent example of 10m loaded vertical that there is
significant difference in the current across the loading coil (not equal) and
lower you go on frequency when antenna gets short relative to wavelength used,
the more pronounced the effect is.

Significance? As ON4UN points out, efficiency is proportional to the area under
the current curve, that is important for loaded antenna designers, and if they
understood this, we would not have the flood of "magical" wrongly loaded,
shortened antennas (like Vincent/UoRI "patented" crap).

Yuri, K3BU.us
just another "dumb" ham

Ian White, G3SEK wrote:
"The phases of the voltages at its (ideal inductor) ends are different, but at every given instant, the currents at its opposite ends are equal and in phase."

When an inductor is placed in a too short standing-wave antenna to correct its power factor, the volts, amps, and impedance at every point on the antenna result from superposition. In general, they vary from end to end. The impedance at any point results from a wave traveling from the feedpoint and a reflected wave from the open-circuit at the tip of the antenna. The reflected wave travels back toward the feedpoint. These waves combine to produce a standing-wave pattern on the antenna much as would be produced on a transmission line.

In a standing-wave antenna, such as Yuri has used as an example, of a coil loaded vertical, the impedance is high and the current is insignificant at the open-circuit antenna tip. The impedance is low and the current is high back 90-degrees from the antenna tip.

One end of the standing-wave, coil-loaded antenna is fed by its capacitance to the outside world. The other end is fed by its connection to the generator. There is no inherent balance in the feed to the antenna or a loading coil contained within the antenna.

A balanced feed to an ideal coil may result in the same current into and out, but an unbalanced feed to a coil will likely result in different currents in and out.

Certainly the same power in and out of a coil will produce differing volts and amps to comply with differing impedances at the input and output.

The extreme example comes from continuous loading. The entire antenna is a solenoid or coil of wire. The impedance at the tip is very high. At its feedpoint, the impedance is low. The current in the coil tapers from one end to the other. Adding conductors to either or both ends of the coil changes the current but does not usually eliminate current taper in the coil.

Best regards, Richard Harrison, KB5WZI

I'm looking for any designs, tips, URLs, etc. that would help me build a 80/160 trap dipole. I've got the ARRL antenna book but it only offers specifics for multi trap (4-5 band) or 80 & up designs. Help!

tia!

There may be a difference in current along the coil, but it isn't a current drop. There is no such thing as a current drop in the sense people use when they say "voltage drop." By the way, Yuri, since you are such an unsung genius of electromagnetic analysis, here's a challenge: design a loading coil for a short vertical radiator that doesn't have, or has only very little, current variation along its length.

My brother made one up for his balcony, got one of those 4x4 post inserts, the ones with the plate on the bottom with 4 holes in it and the two bolts on the side for tightening the 4x4 up, the then placed it in a 15" tire rim and poured concrete into it. It gives it weight and the two bolts allowed him to put some shims in 1st to straighten up the post a bit and then tighten. the post goes almost right up to the rail and the dish hangs over to get him a line of sight as he faces eastward and slightly south. #rd floor of about 15 floors. (Its the tree that causes him problems and 3 times now he has had to do a 4:00 in the morning trimming while a buddy hangs out below with at 2 way radio watching for the security guard and piling the branches in his pickup. Is there a condo law against that LOL.

It's theoretically possible to make small, highly efficient antennas,
but since the radiation resistance of such antennas is low as well as
the loss resistance, the Q is high and the bandwidth stinks.

Ken -

Unadilla has a set of traps that will work for a 75 / 160 or 80 / 160 trap dipole.
http://www.unadilla.com/traps.htm

I will assume a 2-band (80 Phone) 75 / 160 meter trap design. This design only uses a set of KW-80F traps.

From the center insulator, the wire is 63 feet and 8 inches to the trap and 42 feet and 1 inch after the trap to the end insulator.

BTW, Unadilla has just introduced a set of 60 meter traps for those 40 meter and 80 meter dipole users -- that would like to add the 5 channels to their antenna system!

Yes Roy,

It has been well established that the
available NEC engines model extremely
well with conventional designs. That is
not the issue.

Your innuendo regarding 'professional'
customers is silly. In my 67 years, have
been Chief Engineer of commercial radio
and television stations, as well as having
designed commercial radio and
television stations, including the first all
solar powered commercial (5 KW) FM
station in the US. You seem to opine
that the ability to make measurement's
is limited to a only special few.

Since none of your customers are
producing critically coupled designs,

your arguments in this regard are
without merit, and IMO, the intent of
this post was a failed attempt to
reduce my standing.

You claim to be a science minded
person, yet you choose to accept
theoretical results over contradicting
empirical data, and do so, without
even an iota of curiosity.

That is not science, it's closed-minded
silliness! Equally as silly, is your
raising such a stink over 1/3 of a dB...
which will prove to be your Waterloo. :)

73,
Chuck, WA7RAI

Ian, if I ever understood, I have long ago lost track of the raging arguments and consequences.

You are quite correct, of course, in your analysis of what goes on in and around a loading coil. But in the face of such rigid minds and attitudes your attempts to convince people of the errors in their ways by simple logic is doomed to failure.

A solenoidal coil of wire, a loading coil of any proprtions, can be considered to be a continuously loaded, fat, relatively short, single wire, transmission line.

Because of the inductive loading it will have a much higher Zo than a solid cylinder of the same length and diameter.

Its inductance per unit length will be that of the coil.

Its capacitance per unit length will be largely unchanged. For close-wound turns tt will be the same as the solid cylinder. For spaced turns capacitance will only be slightly reduced and calculable.

Zo = Sqrt(L/C) and R is the wire HF resistance including proximity effect.

To simplify, for a first approximation R can be neglected and the line becomes loss-less. If the length of coil is long enough then its radiation resistance Rrad may be high enough to be taken into account alongside R.

The propagation velocity V = 1/Sqrt(L*C) from which phase-shift per unit length of coil can be calculated. (Phase shift appears to be a sore point in the arguments)

If necessary, attenuation per unit length can be calculated from R+Rrad.

The properties of this line, the coil, is now amenable to normal transmission line analysis with a fair degree of accuracy. Accuracy is limited by the accuracy of determining coil dimensions. Such things as the increase in overall diameter by wire diameter matter.

Input impedance can be calculated from the terminating impedance. The terminating impedance is the remainder of the antenna (another transmission line) but for the purpose of settling arguments arbitrary values can be chosen.

The phase shifts relative to feedpoint at each junction along the loaded antenna can be calculated. Some of my programs use the above-described calculating method. But none of them have relative-phase outputs for the simple reason that nobody has yet found any practical use for such useless data and in any case there's usually not enough space on the screen.

All phases are relative. I've a feeling arguments have arisen because of confusion about what phases are relative to. You've been arguing about different things and you can't ALL be that stupid. Unfortunately, communication via newsgroups cannot make use of body-language. ;o) ;o)

> without merit, and IMO, the intent of
> this post was a failed attempt to
> reduce my standing.

The statement about professional users wasn't meant to be innuendo or any sort of slight, but simple fact. I was referring to the aerospace companies, government agencies, universities, broadcast consultants, international broadcast companies, space agencies, and the like that routinely use EZNEC, and some of whom continue to buy additional copies of the professional versions. (Surely you regard these as professional users?) And they don't tell me (or hardly anyone else) specifically the kinds of antenna they design. Since your antenna is seemingly the only one which is incapable of being modeled (other than ones which can't be modeled for well known and documented reasons), you alone must have the key to the magic involved.

The NEC-2 manual is available from the web. It explains in detail how the network model, which is used for transmission lines, is implemented. Surely someone with your extensive professional background is able to

read and understand it.

> You claim to be a science minded
> person, yet you choose to accept
> theoretical results over contradicting
> empirical data, and do so, without
> even an iota of curiosity.

Ah, here we go again. Someone makes claims that contradict known and widely accepted principles. Then the charge is made that anyone who disbelieves is narrow minded and without curiosity, and challenged to disprove the extraordinary assertions. I have no obligation to once more show the validity of accepted science; the evidence is there in abundance for anyone with curiosity to see. It's up to you to back up your extraordinary claims with evidence. All I've seen from you for evidence is a mention of back-yard measurements. This is hardly enough to convince me or any rational person that established physics is wrong. I've even put my money where my mouth is, and offered to pay for a real, objective test of your antenna. That's all you're going to get.

> That is not science, it's closed-minded
> silliness! Equally as silly, is your
> raising such a stink over 1/3 of a dB...

Money talks, and common sense and real world reports take a walk. In most cases anyway. Some companies have already tried and discarded BPL. Problems o-plenty. Maybe others will see the light. The dark side has won a major battle, and Darth Chipster gloateth o-plenty, but the day is not lost yet. My R2 unit, "henry 2k console model", is jumping around beeping and squeaking just itching to join the battle. If they attack locally, I will give them sporadic shots of my BPL death beam via my various elevated radiating devices. I'll have them locking up like a J38 model speedsters hitting a canyon wall. The F.C.C brass should be flogged with leather whips for the obvious disregard of the currents users of the HF spectrum. It's all about money...Nothing else. All the reports of problems with the systems were ignored.
"Except by some owners, who dropped out of the BPL testing"
Also, many claims are pretty hokey...IE: they claim that they can null out problem frequencies, IE:, aircraft, etc, etc. But I hear of problems doing this. I hear it's not really that feasable if they want to maintain proper operation, and I also hear it doesn't really cure the problem, as the "nulling device" is not far from the user.
Take just aircraft alone...We are talking nulling say 2-3 mhz, 6 mhz, 8 mhz, 10 mhz, 11 mhz, 13 mhz, 17 mhz, 21 mhz, 27 mhz, just for a few...I may have missed some military bands, etc...
I have heard of no notching plans for amateur bands, so I guess we have to go to rf noise hell...:(
I bet the system will work great with all those notched holes...Not....

They still will be radiating those freq's on the main lines I would think. It's the biggest money grubbing farce I've ever heard of. Heck, with my radios and antennas, they could probably be blocks or even miles away, and I could still hear it. The Florida experience backs me up on this. I'm not just barking at the moon. Bye bye weak DX....Bye bye weak aircraft signals. Bye bye any rf weaklings...QRp will be extra fun being half the country will probably soon have their ears plugged with digital spew.
But, I bet they will hear me too, if the leakage is that bad...:) It will be a bad day for the empire if my R2 unit joins the fray. I'll keep those BPL techs a hopping all over the neighborhood. Remember,

most of the speculation is about damage to the hams, etc... But don't ignore the damage all the 1000's of hams and other rf emitting device owners will likely cause them. CB's will have to deal with them also, and you know how nasty signaled some cb'ers can get. I hear some 4-5 mhz wide as it is... I don't think they have really fully taken this into account yet. MK

It's not clear why you have a problem with NEC-3 when it was superceded long ago by more-advanced NEC-4. NEC-4 can be purchased by nearly anyone, as a little web research would have quickly revealed. Yes, even you can buy NEC-4. But alas, it also doesn't take into account magical phenomena.

A lousy splice could well act as a completely non-linear diode
detector and spew even more garbage everywhere up and down the whole
RF spectrum. It just keeps getting worse.

As to power line physical specifics kindly consider: To to a large
extent the radiated interference the BPL ISP's might bless us with, if
it ever gets off the ground, is dependent on the physical realities of
the line configurations they use.

Roll back decades ago and the phone companies rather easily beat their
interference problems (crosstalk for one) eons ago by using twisted
pairs of conductors to move comms along their wires. Twisted pairs of
conductors are generally inclined to reject incoming interference and
equally are not particulary inclined to radiate whatever signals they
might be transmitting from here to there analog or digital yes? Of
course. Goes back to some guy named Maxwell, has something to do with
the 3D electromagnetics right-hand and left-hand drive ya batty
"rules" he "discovered".

So it's become quite obvious to me that BPL and HF ham radio could
co-exist quite peacefully on the bands after they install their 3ï¿½
13Kv twisted pairs.

Actually, it's just the opposite. you are stuck on what you THINK is "legal" and what is truly legal. Unless your "balcony", etc., are specifically defined as what they are, and what is included, then they are not technically covered, because the LEGAL definition would be one based on the most COMMON and UNDERSTOOD definition, which is covered by the definition in the dictionary. You can't just randomly call something whatever you want, without providing definition and guidelines and examples, and expect others to know what it is, and expect it to be considered LEGAL.

It doesn't work that way my friend.

No, I am not doing anything of the sort. I am informing you of your mistakes, and your CC&R's FLAWS, and how to correct them, and giving everyone something to think about, and something to base their own RESEARCH ON before diving into anything. If I make one person THINK about something, then it's a good thing.

I also specifically said that "I" would challenge your supposed CC&R's (based on your explanation of their wording, since i haven't specifically seen them to determine the reality of such statements), because i think your definitions and your assumptions are not up to par.

Trust me, one slight mistake in wording can mean the demise of your precious rules.

Still like to mess with you too. ;)

Hi Doc,

Hold up the "taking of office?" You mean like it got "took" before
(as you may recall, no votes above 9 counted)?

In the last election cycle we had a close race for Senate between
Maria Cantwell (D. challenger) and Slade Gorton (R. incumbent) and it
was the Absentee Ballot from the rural counties that gave Slade the
boot and that final count took some several weeks (following his
concession).

In fact, the final count hardly saw a ripple in the ballot calendar.
If you consider the Oregon vote, it is 100% Absentee Vote.

Today the new registrant count has pushed past 1700 with the focus
moving back into the well-heeled suburbs. Same enthusiastic
participation in a traffic of SUVs following me through the parking
lot while I was looking for the designated parking place (I'm driving
a 25 foot RV style mobile registration office for the Office of
Elections and Records).

It is not without its amusing moments, and its irritating moments.
Yesterday had me in a tide pool of University students (their moment
to catch up on registration once back on campus) and they were quite
inventive on how they thought voting should work (with some as lazy as
their parents in the 'burbs). Back in the 'burbs today and this
frantic b**ch demanding guarantees for her mother (at her side).
There was nothing I could offer that was satisfactory and she
dominated everyone's time to get her agenda cleared first. I put up
with that just so far and cut that loose; gave my spiel (the facts of
life and how to cope); and her mother shook my hand while daughter
went into melt-down.

Another fellow with a thick accent asked why we didn't check identity
papers. I explained that if we got more than 1 signature from the
same address and the same voter, he would be visited post-haste. He
then asked what kept a foreigner from voting, I responded "5 years in

the penitentiary."

There's your joke.

Hi Bozidar,

This is one of those cosmic jokes that everyone believes and has no
grain of truth within it whatever.

There is NO necessity of the invention being able to work and it never
has been a necessity (cute stories aside). The Patent as a concept is
first and foremost based on CAPITALISM (remember the cold war?). The
Patent Office WILL NOT grant you a Patent unless you can offer how it
has a market advantage.

If you say your antenna will make your teeth brighter for a nice smile
- you get a number! Do you need to prove it? NO! The only thing you
need to prove is that you thought your teeth got brighter and no one
thought of THAT before. So, if someone builds your design to brighten
teeth, you get to take them to court. And why? Because it infringes
on your INCOME, not your intellect.

There is not one shred of science in any of this - except the words
they use to disguise the fraud.

> My discovery dates to 1988.

Oh really....Why do you say: "Self-similar antennas have been known since Mushiake's 1948 work on self-complementary designs". Did you change names?
I assume you darken your hair? Add some in the middle with spray paint? You would be a definite old fart to have done that in 1948.
Oh...I get it now....You "reinvented" the self-complementary design that was first pioneered by Mushiake and then decided to call it a fractal, being he neglected to use that term when describing the same thing. Crafty little weasel he is, that Chip..Did you invent the dipole? It's a fractal. A simple version, but it's a fractal. I had a storebought fractal UHF TV antenna 30+ years ago. I bought it at radio shack. You'll need to sue them to maintain the status quo. The way I see it, you really didn't "discover" anything. You just picked out an obscure, already known, form of antenna, and "discovered" a new more stylish name for it. MK

## 628. Loading coil behaviour..

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-17 05:35:50 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <ckt0bl$okl$1@titan.btinternet.com>
Source record: 88223

Ian,

The equivalent shunt self-capacitance of a coil obviously affects the magnitude and phase of the current which flows in it. This particularly applies when a high-value loading coil is near to the top of a vertical antenna which is terminated with a very short rod or whip.

(The self-capacitance of an isolated coil is calculable and can be easily checked by using one of these small hand-held antenna analysers to measure a coil's self-resonant frequency extremely accurately.)

In the extreme case, when there is no whip, the only capacitance across the coil is its own self-capacitance. Yet to behave as a loading coil and draw current up the antenna below it, it is required to have a low impedance.

A circuit analysis becomes quite involved. The coil impedance has to be in the form of a series resonance with the length of antenna wire below it. So we have a series resonance in the presence of the coil's shunt capacitance.

From ordinary lumped circuit theory the equivalent coil Q drastically falls, a very large voltage appears across the coil, and a very large circulating current flows around the coil and its own self-capacitance.

Efficiency goes for a Burton and with a high power transmitter either the coil melts or collapses due to voltage-breakdown between turns.

The moral of this story is never to locate a loading coil near the top of an antenna. It also explains why maximum efficiency usually occurs between half-way and 2/3 of the way up.

With an exceptionally good ground maximum efficiency occurs with bottom loading. In which case you don't need a coil in the antenna at all. You can include it in the tuner.

To see how radiating efficiency of a short or long vertical changes with coil height and how coil loss increases extremely rapidly as the coil nears the top of the antenna, download in a few seconds program LOADCOIL from website below. Its quite safe to use the program - there's no danger of setting the coil on fire.

You can slide the coil up and down the antenna from the keyboard and immediately observe how a variety of parameters change. Also copious notes.

It's my understanding they have to not only run the fiber optic cable,
but "reclip" it to the power line every mile or so. In the end they
are basically running a fiber optic feed, but the power line gets it
into the customer's home or business.

I'd really like to see a definitive write up on just how the
infrastructure works and the protocol.

As has been mentioned a number of times, Both Europe and Japan tried
BPL and gave up. Possibly it'll come back to haunt them, but it
sounds like they've already found it an unsatisfactory means for high
speed Internet connections.

>stylish name for it. MK

That life was so easy:-)

No Mark, I'm afraid (for you) there's more to it than that..

You have taken two statements that relate to different things, and tried to confuse people by combining them as one.

I believe the history of self similar antennas has been well documented in my publications, and the relevant excerpts are publicly available.

In any case, this is a BPL thread and you and I have already expressed our thoughts on that subject.

73,
Chip N1IR

>He and his fractal antenna crap have been ridiculed so much on this
>forum (rightly so)
>that he feels compelled to use the BPL issue against fellow hams as a
>weapon.

My dear friend,

This is not the case.

I work with hams and have hams on my board. And, of course, I am a ham. There is no 'weapon'.

The issue is the following:

Does ham radio accept the wireless /telecom revolution, or does it live in the past?

Dual use of spectrum with the proper guidelines and thoughtful restrictions is the way to go, so that millions of folks can share in this evolving radio landscape. BPL will be only one of many adopted technologies in this mix.

What's happened is that a very few vocal hams have gone totally ballistic and used any and all tactics possible to try to kill a new technology called BPL.

My point is that those of us who dissent (relative to those such as yourself) on this matter , and in fact we have a logical, rational, and objective view, should have our opportunity to voice our opinion as well.

The few radical hams who have tried to represent radio amateurs in the United States as a whole, do not,in fact, represent that body.

The FCC must represent the people of the United States, and more specifically in this case, the WHOLE radio amateur service.

They watch out and do what's best for the SERVICE--not a few very vocal hams.

I think the latest modifications to Part 15 are a brilliant roadmap to allowing new technologies to be a viable dual user of spectrum with licensed services. That includes the BPL use of the HF spectrum.

I'm also very enthusiastic about the other technologies that have been discussed here, including, among others, Wi-Max.

Obviously there will be some markets where BPL does well, and others where it won't.

But for a few vocal hams to try to kill a new technology only focuses the spotlight back on us, as, in fact, it has this past Summer and Spring (for example, the front page Wall Street Journal article). And that focus makes us

look antiquated and silly to the outside world.

I don't feel (and am not) antiquated and silly. Are you?

Hams need to move ahead--not just anecdotally-- with new modes and technologies. There is HUGE resistance to that, and the world has and is passing us by.

I think this is very sad, and I cannot condone that.

So this is how one very informed radio amateur feels.

With Best wishes,

Chip N1IR

## 635. Thermal and EM images of antenna ?

Hi,

To illustrate technical articles about EM radiations, I' m searching for thermal images of antennas during transmission ?
Images showing the EM field is welcome too (not radiation pattern but measured in situ and transposed in false colors)

Any URL to suggest ?

NB. I have well found some thermal images of electronic components but not of antennas.

Thanks in advance

Wow...

That's no longer very common.

Some people have run smaller antennas on thermal paper to map the currents/voltages.

But a true thermal digital image of an antenna in situ is very difficult, because of convection currents.

A more common mode is to attach thermal sensors at various points on the antenna and map the temp as a function of time.

Is that what you had in mind?

"Fractenna"
> But a true thermal digital image of an antenna in situ
> is very difficult, because of convection currents.

Huh? Run some high power into the antenna and click the shutter button. What could be simpler (assuming you have the right camera). Obviously need a fair amount of power.

Could model it by simply looking at the current distribution in NEC (current equals heat, neglecting many other factors).

Comnection currents ?? <rolls eyes> Okay, run the experiment in a vacuum chamber <smirk>.

> A more common mode is to attach thermal sensors
> [WITH LONGER DANGLING WIRES???] at

Bull feathers. The leads would *obviously* (duh!!) screw-up the operation of the antenna (unless you're proposing fibre optic temp sensors).

BTW - (giving you the opportunity to change the subject and not answer the questions as per your normal MO thereby maintaining your extreme pompous to idiocy ratio), did we ever sort out who really invented or developed or suggested or discovered radiocarbon dating???????

================
OPPS !!!
The earlier measurements that I gave you were for the KW-80CW TRAP -- the 80
meter CW portion !!! Those earlier dimensions have center tuning at 3.675
MHz for 80 meters and 1.85 MHz for 160 meters (I corrected this above).

The 75 METER PHONE PORTION OF THE BAND using the KW-80F trap should be:

[Center insulator]------60 feet and 4 inches------[KW-80F trap]-------45 feet and 10 inches------[end]

The 75 meter center frequency at 3.875 MHz and
the 160 meter center frequency at 1.85 MHz

Source record: 88236

>Huh? Run some high power into the antenna and click the shutter button. What
>could be simpler (assuming you have the right camera). Obviously need a fair
>amount of power.

Thermal images register differentials in temperature . The lower horizon and ground are usually between 200-300 degrees Kelvin (with no water vapor, the horizon looks much colder) and it is thus an issue of looking at temperature changes that are typically a few degrees or less.

Antennas have surface areas and thus heating and cooling rates. The instantaneous thermal temperature is indicative of the point where these rates come into equilibrium.

The cooling rate will be affected by the surface layer of air. Usually, convective cooling is a big factor and biases the true temperature at the surface. Thus the actual temperature in air is different from that in a vacuum. I don't believe you are referring to a vacuum.

Electrical thermal probes can and are used.In order to have minimal effects on the current of the antenna, they are attached by a small but highly heat conductive paste--an electric insulator as well-- and then choked. Usually the leads are run normal to the radiator surface.

The amount of power you need is indeed, not small. Fairly large metal surfaces dissipate heat moderately well through radiation and air convection, so you could be burning up a fair amount of power and not be able to detect it with any great precision. If the heated surface is small, i'ts much easier. Most antennas of interest do not have small surfaces or lengths.

Hope this helps.

>Bull feathers. The leads would *obviously* (duh!!) screw-up the operation of
>the antenna (unless you're proposing fibre optic temp sensors).

Actually, the real problem is that the RF can screw up the very sensitive probe.

The trick is to do on-offs of antenna power, and register the temperature on the offs. The duty cycle must be adjusted so that the equilibrium temperature is being sampled properly. Most of the time, the temp drops noticeably after 30 seconds to a minute. In some cases, the probe can be quickly attached and then detached during the off cycle.

It's fun to do. Som experimenting shows how to mitigate 'to measure is to disturb' issues.

Best,
Chip N1IR

I believe you're about half-way to proving that Thermal Images are impossible. What next? Santa Claus?

Perhaps the delta between our positions is that if the temperature increases are not significant, then I'm assuming that the information is not of value (for the purposes that I'm assuming). In other words, a flame test without the flame. Perhaps you're assuming another (more academic, less practical) purpose.

I've seen lots of foolishness in this general field (w.r.t. cell phones, fake heads and measuring temperatures- pure rubbish and a lack of common sense). The world would be a better place if they sent most of the researchers in this field on a one-way trip into outer space. The whole field seems to be infested with idiots (perhaps too much time experimenting with cell phones?).

> ARRL "bibles" like Antenna and Handbooks :-(yep, latest 2005 "revision"
> still
> has it in it)
>

I think you are taking what ARRL says out of context. I will quote from page 16-7 in The ARRL Antenna Book, 20th edition...

"The loading coil acts as the lumped constant that it is, and disregarding losses and coil radiation, maintains the same current flow throughout. As a result, the current at the top of a high-Q coil is essentially the same as at the bottom of the coil. This is easily verified by installing RF ammeters immediately above and below the loading coil in a test antenna."

Don't overlook the part about disregarding losses and coil radiation. And, don't overlook the part about verifying the current with ammeters. Have you done that?

The ARRL book doesn't even recommend using a loading coil with an 8 foot whip on the 10 meter band. Read the whole chapter. Note that your "coil" is 7.4% (6.7 degrees) of the antenna system length. It is no longer the lumped device which is assumed in the book. Please repeat your experiment on an 8-foot whip at 40 meters and then verify with current meters.

If you can still make the same assertions for 40 meters, submit your findings to the ARRL for publication. If they find them worthwhile, I'm sure they will publish them.

John

|
|Money talks, and common sense and real world reports take a walk. In
|most cases anyway. Some companies have already tried and discarded
|BPL. Problems o-plenty. Maybe others will see the light. The dark side
|has won a major battle, and Darth Chipster gloateth o-plenty, but the
|day is not lost yet. My R2 unit, "henry 2k console model", is jumping
|around beeping and squeaking just itching to join the battle. If they
|attack locally, I will give them sporadic shots of my BPL death beam
|via my various elevated radiating devices. I'll have them locking up
|like a J38 model speedsters hitting a canyon wall. The F.C.C brass
|should be flogged with leather whips for the obvious disregard of the
|currents users of the HF spectrum. It's all about money...Nothing
|else. All the reports of problems with the systems were ignored.
|"Except by some owners, who dropped out of the BPL testing"
|Also, many claims are pretty hokey...IE: they claim that they can null
|out problem frequencies, IE:, aircraft, etc, etc. But I hear of
|problems doing this. I hear it's not really that feasable if they want
|to maintain proper operation, and I also hear it doesn't really cure
|the problem, as the "nulling device" is not far from the user.
|Take just aircraft alone...We are talking nulling say 2-3 mhz, 6 mhz,
|8 mhz, 10 mhz, 11 mhz, 13 mhz, 17 mhz, 21 mhz, 27 mhz, just for a
|few...I may have missed some military bands, etc...
|I have heard of no notching plans for amateur bands, so I guess we
|have to go to rf noise hell...:(
|I bet the system will work great with all those notched
|holes...Not....
|
|They still will be radiating those freq's on the main lines I would
|think. It's the biggest money grubbing farce I've ever heard of. Heck,
|with my radios and antennas, they could probably be blocks or even
|miles away, and I could still hear it. The Florida experience backs me
|up on this. I'm not just barking at the moon. Bye bye weak DX....Bye
|bye weak aircraft signals. Bye bye any rf weaklings...QRp will be
|extra fun being half the country will probably soon have their ears
|plugged with digital spew.

|But, I bet they will hear me too, if the leakage is that bad...:) It
|will be a bad day for the empire if my R2 unit joins the fray. I'll
|keep those BPL techs a hopping all over the neighborhood. Remember,
|most of the speculation is about damage to the hams, etc... But don't
|ignore the damage all the 1000's of hams and other rf emitting device
|owners will likely cause them. CB's will have to deal with them also,
|and you know how nasty signaled some cb'ers can get. I hear some 4-5
|mhz wide as it is... I don't think they have really fully taken this
|into account yet. MK

Exactly.

I'm pretty sure that I've mentioned much of the following before but just in case...

My power company is a rural cooperative. It serves 29,000 customers spread over three counties. (one of these counties is larger than a few states.) It has 2900 miles of line (and I don't think that covers the 600' of underground feeder from the pole to my house). They serve from the river bottom land near Tucson to the top of a 9800' mountain and a community on the Mexican border. The company is also my ISP.

A few years ago I was fighting powerline noise and not getting a lot of help from the company. It wasn't for lack of interest on their part, they just didn't have the resources or trained personnel to isolate the problem(s). I basically wound up instructing their linemen about what to try.

During this time I wound up in contact with the company VP in charge of new technology. We had an interesting one-engineer-to-another conversation wherein he told me that they had experimented with a system to read customers' meters remotely using "common-carrier" signals on the lines. Sending guys around the service area in pickup trucks once a month to read meters was a big expense so they had a compelling motive to pull this off. They failed.

Even with very narrow-band, low-speed signaling, they couldn't even read a meter once a month. They finally went to meters with transmitters in them that can be read without the guy having to get out of his truck and walk around with the rattlesnakes.

And they're going to supply me with high speed Internet over the same wires?

It has already been proven that Santa Claus is impossible. Too many chimneys to crawl down (let alone up: Claus is morbidy obses as I recall)) in one night...

>Perhaps the delta between our positions is that if the temperature increases
>are not significant, then I'm assuming that the information is not of value

You miss the important issue. Heat is not dissipated at a point but over a surface. If I take a soldering iron, for example, and distribute its 40 watts of heat across a strip of 2 feet by 4 inches, for example, it won't get very warm in a differential way to ambient.

That re-distribution of heat across a larger surface area is how heat sinks work.

Ergo, the increase in --temperature-- at a point of measurement--or even across an area or region-- can be small, even though the total amount of ohmic loss may be high.

Thermal cameras register differential thermal radiation losses, not convective losses (per se). And the heat is distributed across a surface, not a point.

You can't take a picture of an antenna outside, and learn much about its ohmic loss, for example. (Too much convective cooling). Not unless its ohmic loss is confined to a small area, the air is rarefied and windless, and thus the temperature differential is a few degrees or more and indicative of bona fide radiative thermal heating/loss.

Hope you learned something:-)!

Best,
Chip N1IR

Hmmm.. where are the thermal images of "antennas during transmission"? All I see are simulation graphics, not antennas with power running through them.

I agree with you, I am no wiser. But I've been told many times, over many years, that I'm precocious. You should be happy that I plateau'ed early:-)

I'm enjoying the wisdom immensely now that I have the grey hairs to go with it. Not a cause for sadness but celebration, if any:-)

Thanks for thinking of me and best wishes.

## 653. So, where does one get aluminum tubes for antenna construction?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-17 16:58:00 UTC
From: Doug McLaren <dougmc@frenzy.com>
Message-ID: <swxcd.14048$Rf4.6903@fe2.texas.rr.com>
Source record: 88248

I'm looking to make a 2m/70cm yagi antenna for working satellites.
The plans are out there, and it seems quite simple. (Or I could pay
$73 to Arrow Antenna, but I'll give it a shot myself first.)

So I hit Home Depot, and the closest thing I found to the approprite
beams was 1/8th inch steel rods. (Basically piano wire.)

It ought to work, and is stiff enough to not bend much under gravity,
but it's heavy, and I'll be holding this thing ...

The local hobby shop has more piano wire that's smaller, but it's
still steel, and as you get smaller, it looses the needed rigidity and
it sags too much.

The instructions suggest hollow alluminum tubes, which should be light
and strong, and a good conductor to boot, but where can I find these?

Also, I've seen Yagi instructions that suggest a that the beams not be
insulated from the boom, and I've seen instructions that say they
should be insulated from the boom (or the boom should be an insulator,
like PVC pipe.) Does it make a big difference? Does it affect the
dimensions of the antenna?

Thanks in advance ...

aluminum tubing can be found at industrial pipe suppliers, or for short pieces you can get tent poles to cut up. welding rod is another commonly used material, copper pipe is another one for small antennas. some people also use steel electrical conduit.

Insulating the elements will change the size they need to be... or you could look at it that when you don't insulate the elements from the boom they usually get shorter because they look fatter at the middle. there are arguments for both methods, but if you use a metallic boom i wouldn't insulate them because its more work if you don't have the proper tools and insulators handy, if you use pvc or something else then they will be insulated anyway.

You might try looking at a sporting goods store for the elements , that is what the Arrow antennas started out as. Texas towers is a place you can order from.

The instructions must be followed exectally at 2 meters and above. The elements must be the same outside diameter. They can be solid or hollow without a change in length. If the boom is a nonconductor , that must be used, if the elements pass through and are insulated from the boom that must be done. The boom will have an effect on the elements almost as the same diameter as the boom diameter. While an inch or two might not make much differance on the low bands, it could put a 440 mhz antenna out of the band. You may be able to tune the swr to a low value but the patern will be way off and the antenna may not have much gain.

The antennas are not that hard to build.

Hi,

Even if the difference is not important vs. ambient air, a good image
processing will improve it.
This is not the problem.
The first step if to find someone able to picture it...

Hi,

We can also do record such images in a lab. In a cold chamber (<10°C or
lower) and sending +1 kW tunes in the antenna
I am sure that with a sensitive thermal device like those sold by
http://www.x20.org/ we can do it.

Most major cities, and smaller ones too, will have recycling yards
that also sell all manner of alum, steel, stainless, brass
etc. Quite a variety of extrusions can be found here. Usually the price, in
my area san diego, is about $2 a pound. These are great places to get stuff
for building antenna

Hi Art,

While this was the common theory many years ago, there other ways to get
gain from an antenna other than boom length and number of elements.

ie On 2m we are able to get 11.2 dBd on a 45inch boom with 3 elements
stacked 2 wide. Yes, this is range tested see results at
http://www.csvhfs.org/ant/CSANT04.HTML

Around here several mom&pop hardware stores carry Al tubing in 10 foot
lengths up to 1-1/4 OD. Also, building supply stores; not Home Depot or
Lowes. I would not use steel elements. For 432, you might be able to use
chunks of Al ground wire. Of course, there is Texas Towers, but I think the
longest piece you can UPS without a surcharge is 6 feet.

Also, try your nearest Welders Supply- for brazeing rods, tho, not aluminium,

would believe these are superior to piano wire! and is available in different diameters, and lengths, and certainly better than most copper, or aluminium of the same gauge in non-malialibility (more weight support if a bird lands on it) Jim nn7k

Hi Roger, we're really too close to need the internet--we should be using smoke signals instead. I'm in Mt. Pleasant, 26 mi from you in Midland. I was licensed in 1933 as W8KHK, and from then until 1940 I was the only ham in Isabella County. I live in DeLand, FL from Nov 1 to May 1, and in Mt. P the rest of the time. We should meet some day. Did you know the late Paul Woodland, W8EEY? He was originally from Alma, but moved to Midland, Bookness St off Eastman, after WW2.

I'll be going through Midland tomorrow to pick up my XYL at MBS, but won't have time then to make contact with you. Guess it'll have to be next year after we return in May.

C ya later,

Walt Maxwell, W2DU

If you started your legal argument with "It says in
Webster's dictionary...", you'd be laughed out of
court. The legal field frequently uses terms in a
way that is more precise than the definitions in
your "dictionary", and that is why our CC&Rs begin
by defining "Unit" and "Association" and "Owner" -
terms for which your "dictionary" wouldn't have a
precise-enough definition, and why they must be
defined within the document itself. That is the
situation in most fields, in fact - everyday terms
don't have the same meaning that they do in
specialty fields, and *most* people understand
that.

>impedance along the length of the inductor whether straight or coiled.

I was going to get back to you about that (but Life intervened), to say that I agree with your entire analysis of standing waves on antennas... except for that one point.

We need to be very clear about the difference between an ideal inductor and any practical inductor. An ideal inductor has only one property: inductance. It does not have length, diameter, self-capacitance, parasitic capacitance or any of the extra properties that a practical coil has. Let's ignore those for the moment, and try to understand how an antenna is loaded by pure inductance alone.

The behaviour of loading inductANCE does not not involve any variation in current between one terminal of the inductance and the other. It cannot, because that is not one of the properties of inductance - not ever, in any circumstances. With a pure loading inductance, the current profile on the antenna has to fit the constraint that the current immediately above the inductance must be equal to the current immediately below it.

In the real-life case this is not necessarily true - but we need to be absolutely clear that any difference in current between the top and bottom of a practical loading coil has to be due to those "extra" properties mentioned above. It is not due to the inductance alone, because inductance alone doesn't do that.

Unless we understand this fundamental point about how an antenna is loaded by pure inductance, we have no hope of understanding how real-life loading coils actually behave.

Could be :)

Back in the 80's, per my specifications, my employer bought some
partial-discharge (corona) test equipment from the James Biddle
Company.

I took a one week long course at their facility on the theory and
practice of partial discharge testing. There were about a dozen
students from various companies in attendance.

One of them was a fellow from Canada who had owned his own cable
manufacturing company, sold it and was then a consultant for the
company. They manufactured HV coaxial cable for power transmission.
I learned that many islands get their power from mainlands via
underwater lines.

Today, coax lines rated to 400 KV are not uncommon. Keep that in mind
if you want to QRO :)

Hi Doug,

http://www.mcmaster.com

McMaster-Carr has massive amounts of just about anything at reasonable prices.

They ship from all over the country, I got my 6' 3/8" al rod next day delivery

for the ground ups ship fee ! (atlanta whse to my qth in tn )

Their website is very fast and works great over dialup or faster connections.

Good luck with the project

Al

## 680. Here's what some think of BPL

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-18 01:22:52 UTC
From: Mike Coslo <mcoslo@adelphia.net>
Message-ID: <D5ednaKM9Jt0h-7cRVn-uw@adelphia.com>
Source record: 88175

http://www.technewsworld.com/story/37378.html

This fellow pretty much sums up what I think about BPL, except that I don't even give it a chance in rural communities.

BPL is a exceptionally flawed method of DSL level "broadband"

I am surprised that some would think of it as anything even remotely modern. It is old old stuff.

There is only one way that BPL can even remotely start to get off the ground.

That is if the rules are rewritten regarding interference. This will mean that the BPL signal MAY interfere with any other service, and that no other service may interfere with BPL. This would be a complete reversal of part 15.

Won't it be something when all the power companies find they *have* to replace all those old noisy transformers that hams have to end up getting Riley to send them a nastygram for?

The power lines are not particularly clean. lots of loose wires and bad transformers and insulators with problems. THey might not be much of a problem now, but they will be a problem...

Then when the neighbors start using their treadmill and it wipes out the BPL signal?

And hmmm, the rules have been rewritten about those wonderful unlicensed part 15 devices, so I guess that the BPL customer can't do anything about it?

But seriously, BPL will probably suffer an early and quick demise. What I am really worried about is if the part 15 rules are rewritten. Even if the rules were specifically written to exclude BPL (talk about a direct admission of technical inferiority) it will be a foot in the door for other industries that would like to not have to put up those fussy FCC regulations.

Since 1953 Belrose article in QST, in all ARRL Antenna Books and Handbooks it is shown that current across the loading coil (mobile or loaded antennas) is uniform, while ON4UN Low Band DXing shows and explains it right.

I will have some more samples modeled with EZNEC and one of these days comprehensive article on the subject. Jus' need some free time.

Yup. The Power lines are really great for mushing up a digital signal.
Round off those edges and lotsa reflections. The fiber will be there.

What is the attraction of getting your digital signal on your
powerline? Heck if I had a laptop, it means I have to connect it to the
wall again - unless I run wireless - and then I might as well run wi-fi.

The haunting will be on our end, especially if part 15 is rewritten to
accomodate BPL. BPL will fail, but part 15 will go on until it is rewritten.

Texas Towers sells seamless, hard Al tubing in sizes that nest
correctly. It's not flimsy and it's not particularly cheap but it is
the correct material for beam antennae. For small (UHF and up) stuff,
use the hobby shop nesting brass tube and rod.

Russ

5 Watts will do it! If you are running high power at your home, you'll likely knock out BPL for miles around.

I would never suggest deliberately interfering. It seems as if almost anything will interfere though.

I've tried the Al foil thing, and it is too fragile IMO. The foil fails at the connection points, and the acidic nature of modern rain tends to wreck it otherwise. What I made was destroyed in a couple months. The white gunk that forms on regular tubing over time, and pits it, goes the whole way through Al foil, which I think has only one side! ;^)

On this subject, has anyone tried that aluminum tape? That stuff is a bit thicker, and the wider stuff might have nice BW qualities, as well as be pretty stealthy.

The secret is: "arrow" antennas are made from arrows. Yes, archery arrows.
The hardware that attaches the arrows to the boom is (again) arrow hardware,
that's used for mounting certain types of arrowheads to the arrow shafts.

Oy, seems anything will turn into a fight, these days! 8^)

Here is what I suggest as a low tech and perhaps a bit silly solution.

Get a number of aquarium temperature sensors. these are the liquid
crystal type that is put on the outside of the tank, with the
temperature indicated by color change. Place on the antenna with the
number of stickers chosen by your desired resolution.

Experiments should be run on a calm day, and ideally at the same
temperature (although you can calculate for the differences) each time.

Transmit, and check, record, and enter into a program that can map the
results for you, or map it out manually.

Binoculars may be needed to see the tape!

This is not as glamorous as a thermal imaging camera, which would have
it's own set of problems, but it should work, and be quite inexpensive,
requiring only more time on your part.

Another approach you may want to take is the Arrow Antenna concept,
but built of WA5VJB's Cheap Yagis. Cheap Yagis work great and have
simple tuning requirements. I did a Google search and came up with
someone who had done exactly this.
http://www.g6lvb.com/HomebrewArrow.htm
There is a link in the article to a page with Cheap Yagi dimensions.

A somewhat smaller antenna is a combination of a Yagi (although you
could easily use the Cheap Yagi design) and a Moxon.
http://www.qsl.net/vk3jed/2m70cmant1html.html

http://on6sat.com/links/ is an extensive list of links related to
satellite operation, with lots of antenna links.

Good luck

I'm not at all insisting on your testing your antenna -- I have no need to. NEC-2 and EZNEC are perfectly capable of accurately modeling it, and accurately show the gain and pattern it will have in practice. Its operation is simple and easily understandable. I'm entirely satisfied that I understand how it works and what its performance is.

My offer, which I think was generous, was to pay the bill if a test showed your antenna to meet the claims you made. I'm not offering to test your antenna for you. You've once again chosen to fall back on your back yard test and creative pseudo-scientific theory to explain the claims you've made, rather than to show the world, at no expense to you, that the claims are valid. That's up to you. I'm not obligated to disprove your extraordinary claims.

Ian White, G3SEK wrote:
"The behaviour of loading inductANCE does not involve any variation in current between one terminal of the inductance and the other."

Yuri has attached a photo in this thread again of an antenna loading coil in action as a psrt of a too-short vertical antenna. RF ammeters are mounted in series, one at the coil top and one at the coil bottom. The lower ammeter clearly shows more current than the upper. That`s exactly as should be expected.

The too-short whip above the coil has an impedance consisting of a high capacitive reactance and a few ohms of radiation resistance. It`s the coil`s job to cancel the capacitive reactance so it doesn`t oppose current into the too-short whip.

Pure inductance alone can cancel pure capacitive reaxctance.

In an antenna loading coil as used in a "Texas Bug Catcher", the coil resides about in the middle of the antenna. The coil has length and current, the two factors which produce radiation.

The Bug Catcher is approximately a 90-degree antenna, including the phase delay in the loading coil/. ON4UN shows in Fig 9-22 on page 9-15 of "Low=Band DXing", a center-loading example which may represent the Bug Catcher

The current taper shown by ON4UN is similar to that shown by other authors deliberately and unmistakenly.

A pure series inductance invokes a phase lag. This would be 90-degrees in a pure inductance but we always have some resistance which reduces the phase lag to less than 90-degrees.

In olden times, chokes were often called "retard coils".

Best regards, Richard Harrison, KB5WZI

Hi Richard,

And it is EXACTLY how it is forecasted through modeling. The real story here is how to mis-use modeling to contrive a different answer to this shaggy dog story.

The last gasp through this stale wheeze had us waiting for the snows to melt so Yuri could replicate the measurements of fish tank thermometers - as the skies darken yet again for another winter's snow, how long will this take to resolve? NOTHING new has been added to the subject and it seems this discussion has devolved to the level of a bunch of hoary denizens sitting around the fire and spitting into it for entertainment.

I've read that about three times, and it still doesn't really make any
sense...

> The few radical hams who have tried to represent radio amateurs in the United
> States as a whole, do not,in fact, represent that body.

The ARRL is composed of only radical, ballistic, troublemakers? Damn,
maybe I should apply for a membership after all....
>
> The FCC must represent the people of the United States, and more specifically
> in this case, the WHOLE radio amateur service.

They screwed the pooch on this issue, if they have the WHOLE radio
amateur service in mind...Not to mention, others live there also..."HF
spectrum"
>

> They watch out and do what's best for the SERVICE--not a few very vocal hams.

Bullcrap....They do whatever the big money dictates...And maybe who
can bend over the farthest....Whoever ramrodded this BPL crap through,
probably needs a jar of vasoline...
>
> I think the latest modifications to Part 15 are a brilliant roadmap to allowing
> new technologies to be a viable dual user of spectrum with licensed services.

I've got news for you. Dual use of the HF spectrum, with the exception
of SS, will never work. I think the new modifications are a primetime
cluster#$%@ of ignorance.

> That includes the BPL use of the HF spectrum.

That means BPL most likely taking over the HF spectrum...It will
become so trashed with digital spew, no one else would want to use it.
>

>
> Obviously there will be some markets where BPL does well, and others where it
> won't.
>
> But for a few vocal hams to try to kill a new technology only focuses the
> spotlight back on us, as, in fact, it has this past Summer and Spring (for
> example, the front page Wall Street Journal article). And that focus makes us
> look antiquated and silly to the outside world.

Again, pure crap. I read the letter from one of the powerline
empiretts...
She made herself look silly to the outside world, due to all the
blatant misconceptions she had about hams...IE: most still use tube
gear, most are inbred CB wannabees, etc...You should read the letter I
sent her. I gave her a complete front end alignment free of charge. So
did about 15,000 other hams I think. Some, who were VERY up to date on
BPL technology. Hams are not against new technology. Hams are against
it sharing the same frequencies as an existing technology. There is no
good reason for it. AT ALL!
>
> I don't feel (and am not) antiquated and silly. Are you?

You may not be antiquated, but you are without a doubt, one of the
silliest bastards I've ever come across on usenet. You can take that
any way you want...
I'm sure many will back me up on this conclusion.
>
> Hams need to move ahead--not just anecdotally-- with new modes and
> technologies. There is HUGE resistance to that, and the world has and is
> passing us by.

Pure and simple horsecrap...BPL is *NOT* an amateur radio related
endeavour.
We do NOT need non amateur radio endeavours, and the resulting digital

spew, in *OUR* amateur bands.
>
> I think this is very sad, and I cannot condone that.

Another day, another $2.31... Next...
>
> So this is how one very informed radio amateur feels.

That statement is open to further debate....MK

That is not exactly what the Technology News has to say
http://www.technewsworld.com/story/37378.html
They basically say it doesn't look promising as a business model and
the infrastructure isn't in place to use it yet, except for a few test
sites. It's inefficient, expensive to install, and is least likely to
serve the sparsely settled rural areas for which it's being touted.

You know what the trouble is with us amateurs is ?

We are stuck in the analogue age... We should all be using digital
communications by now..

Wasn't there a time when amateurs were ahead of commercial design?

Now all we do is complain when the commercial world brings out new
technology that
causes a problem with our old technology.

Look at the big picture people... We are still using analogue
communications..
Blimey , even my home phone is digital. My CD player is digital, my TV is
digital.

That's my 2 pence worth ( about 4 cents... )

Chris,

It is important that you express care when making statements that are false.

It's quite OK with me if you take a strong tone or attitude. It's not in your best interest, however, to posit things in a false light for the sake of taking things over the top against me as an individual.

You seem to have concerns about fractal antennas, which I have been forthcoming about and dead honest.

I have no continued interest in 'defending' fractal antennas in this forum, for the simple reason that the technology and the science are proven, accepted, and well beyond this point.

You asked me about a specific design, and I provided you the info.

I also provided you info on how it was tested, but you chose not to accept that info.

That's all there is, Chris.

Now, be the nice guy you are and don't seek to be a defamer or propagandist.

As for BPL, it would be wonderful if all the (few) uppity hams upset with BPL could target an individual to accomplish their goal. The reality is that the battle is lost, for the simple reason that there is no battle, and attacking me only, apparently makes ham radio look bad in general; IMO.

I am not the only one who feels, or notices, how backward we are as a group of communicators from a applied use of technology viewpoint. We need to understand that HF communications needs to be advanced by hams AS hams, and not revered in the same mold from 1967.

BPL will now be decided in the marketplace, not the histrionic hyperbole of a few hams. Accept it.

I hope you will agree with me that this was always the case, but a few emboldened amateurs failed to grasp that reality.

Have a pleasant day.

If all the consultants had got info right--especially the ones who love to talk in the press-- then you and I would probably be using technologies that died miserably, which they touted as god's gift..

It's a big market and there are lots of ways to play. BPL has a good shot and will undoubtedly have a worthwhile niche.

As someone who deals with business cases--daily--I find it suddenly amusing that many hams--present company aside-- think they know anything much about it. I can't wait to hear conversations on 75M about 'entry barriers' and 'crossing the chasm' and 'risk management'. Sure beats 'how's the weather?'

I made no false statements.

You did, indeed, provide the "data", but you never answered when I asked you for contact information for the range that performed the tests, or a website not owned or run by your "company" which can verify the figures you gave.

I can type out db gains off the cuff, too..

The fact is you didn't respond to that question.

You also didn't respond to the question about who had so much information on me. You got the callsign right. You have internet access. You know where to go to look up a HAM's email address, if they have one. You apparently refuse to understand why someone wouldn't put their real email address on usenet. And finally, you apparently refuse to take the steps necessary to accurately and completely answer questions posed to you, without evasion of any sort.

So where's the lie?

Source record: 88206

three possible reasons..

the meter is not as accurate at low power levels. this is common on meters driven by line power. below some level the simple diode rectifier just doesn't drive the meter movement, since this usually happens on the reflected side first due to the lower voltage the readings can't be trusted at low swr's or low power levels.

the other possibility is that you have something breaking down causing a change in swr. while this is unlikely at only 100w, it is possible. this would normally cause a sudden jump in swr as power is increased and often results in erratic indications.

and lastly, the transmitter is poorly adjusted. as power is increased you may be generating more harmonic content. if the antenna reflects the harmonics back they can add to the swr. this is often seen in tube finals or high power amps, when being tuned the swr reading after the amp changes as the tune/load controls are adjusted, even if the power indicated stays constant.

There is no such thing as a "current drop." As for Yuri declaring victory, that's easy enough to do since the person he's declaring victory over, Tom Rauch, isn't bothering to refute him on this newsgroup.

Then again, the regs and band plans have us bound up pretty tightly.
Not a whole lot of room left to experiement with modulation schemes.

Antennas are still wide open, but it seems a lot like aerodynamics, all the
good work was done in wwII, and not much progress since, except for tweaks.

<bigfathhairybiker@MAILhot(swapemround).com> wrote:

>You know what the trouble is with us amateurs is ?

Hi Mike,

Sure, some of them don't know what "digital" is, your posting contains examples which follow below.

>We are stuck in the analogue age... We should all be using digital
>communications by now..

As an isolated statement that is true. There are more modulation modes now than there were 20, 30, 40, 50 years ago, and many of them are digital based - BPL is baseband, not modulation, however I will let that pass for further discussion.

There are also digitally based methods of generating an RF frequency of a purity that exceeds all the current Ham radio equipment commercially available, but those methods are not widebanded trash generators. Clearly, digital methods are not necessarily interfering methods - except in the hands of commercial interests with less than amateur talent in marketing dominating their engineer's efforts.

>Wasn't there a time when amateurs were ahead of commercial design?

This is called being stuck in the time warp of 1928 innovation and WWII's need to draft both the Ham and his transmitter because of a shortfall of equipment. Since then, except for rare achievements like exploring Spread Spectrum (which the FCC hamstrung) it has been follow the market.

The Amateur community is not about being a class of inventors, but rather a resource pool of savvy and experienced technicians and engineers who could be relied upon to reign in the self-interests of decadent commercialism. This dialogue is one clear and obvious example of both that talent's exercise, and the stonewalling of a crypto-fascist administration.

>Now all we do is complain when the commercial world brings out new
>technology that causes a problem with our old technology.

I presume by the inclusive nature of "we" that you are against new technology? If not, then your argument contains its own self-negation. If so, then your argument is what psychology calls "projection" WE do not necessarily share YOUR problem.

>Look at the big picture people... We are still using analogue
>communications..
>Blimey , even my home phone is digital. My CD player is digital, my TV is
>digital.

And in this last statement, "we" find your poor understanding of the problem in general, and the concept of what digital is, in particular.

Your TV is analogue even if your remote tuner is digital. Even there, your remote tuner is not digital, it is CW (albeit with a different code set). CW is one of the oldest modes around. That IR beam that communicates with your big bottle across the room sends a chopped light beam that is in now way OCTAL nor HEXIDECIMAL but closer to Baudot. This is about as close to "digital" as you are in the living room, and Amateur equipment has had this advantage for quite a long time now (Baudot has been with amateur service for at least 60 years).

As for your home phone or CD player, if you have any impression that you are actually listening to "digital" you are indeed the product of genetic manipulation and should rush a sample of your DNA to the nearest patent office to claim your birthright is actually intellectual property.

Again, any "digital" property found in these commonplace AND LINEAR devices is and has been found in Amateur equipment for a very long time now. If this is news to you, you can then appreciate your unique problem of "projecting" your lack of understanding on others and calling them out for being against technology.

We have access to every OTHER Hertz in bandwidth across the spectrum.
Half for us, half for them. Just don't expect all (or significant
portion) of your half in any one place - that just wouldn't be fair
now, would it?

Keep in mind, this is the kinder, gentler compassion we've been
promised and by all CIA investigations into the matter, they've been
overwhelmingly successful (please don't ask for documentation).

Richard:

Thanks for the heads up. I know Fracky from way back. I've been here awhile, but mostly I just read, because I don't have much "on topic" to contribute that those who are much more learned (such as yourself) haven't already shared. Occasionally I can relate an experience I've had with mobile operations that might be helpful, or rebut idiocy and malformed opinions as they're stated.

So thanks for the concern. Keep up the good work here in the NG.

There are some serious limitations to digital voice comms that make it not work so well for our purposes. Bandwidth issues, believe it or not.

Another problem I note is that I was reading a review of a unit that will interface between the microphone and xciever. I was reading along with interest - it sounded pretty good - then at the end of the article they note that you have to receive the whole transmission, or you receive nothing. No tuning across the bands looking for a signal. Perhaps the ARS should be channelized like CB?

Comparisons with cell phones are amusing because the quality of those little POC's is by and large unacceptable IMO. "Can you hear me now?" 8^)

There is a table of data calculated by VE7BQH for a large number of
different yagis, at:
http://www.ifwtech.co.uk/g3sek/diy-yagi/ve7bqh.htm
(These are not calculated by NEC, but by another very adequate program.)

You can draw your own curve from the data in the L(WL) and Gain columns.
Since all the data have been calculated by the same person, starting
from the antenna's mechanical dimensions, and using the same program,
this removes a lot of variables.

You will see a broad trend of increasing gain with boom length, but
there is still a lot of scatter due to variations between different
designs. Also bear in mind that gain isn't everything, and a long yagi
that has been maximized for gain may be a poor antenna in other ways,
such as sidelobe levels, ease of pointing, sensitivity to water on the
elements, ease of matching etc.

Drawing gain curves is a fun activity... but don't try to read too much
into them.

If there is a digital mode that uses less bandwidth, sounds at least
acceptable to enough people, and allows me to tune my radio in a normal
fashion, I'll hop right on it.

And of course, we have to remember that there is an inertia based on
the need to have people to talk to. If I have the nifty new digital mode
of communications, how much fun is it going to be if I only have three
other people to QSO with? These things take time, and I may assume that
Mark has a digital rig?

Modern digital HF voice can be hi fidelity; narrow bandwidth, and experience few dropouts. It is superior to SSB, in any case. I don't see why it is not a superior solution for amateur service HF needs.

The next trend will be software defined radios/cognitive radios, for which we have already got a simple taste of in recent years with Kachina, and so on. The thing that will be new to us is the incredible flexibility of the choice of waveform and frequency.

It IS a real shame that hams, as hams, have not led the telecom revolution/evolution in the last decade. We had a shot at being the first

practical and major adopters of spread spectrum a generation ago--that fizzled.

It may very well be that changes in the mode allowances on HF will encourage some major innovation.

Do you now realize that SSB has had a longer run than AM as the dominant mode in the ham community? Other than legacy use in military and public service, where else will you find such an allegiance to SSB?

SSB is noisy; not optimized in bandwidth; and of poor fidelity. CW even beats it for S/N for a given link.

SSB is especially prone to broadband low noise levels. All the more reason to move it aside for better modes.

> accurately show the gain and pattern it will have in practice.

Methinks your opinion is in error, Roy...

NEC2d /NEC4 may well be capable, but I
have my reservations about your EZNEC.

I've been looking through your Ver. 3 manual
and I cannot find any reference to non-
radiating networks: two-port network
specification (NT)) or the thin-wire option: the
Extended Thin-Wire Kernel (EK). Nor do I
see these functions in your control panel.

In looking through the NEC2d docs, my
concern regarding NEC's ability to 'see'
"induced current at one or more points in a
structure" has been put to rest. However, in
Section V of the NEC2d docs (p 62), quite a
lot of attention is given to (1) source
modeling and (2) nonradiating networks.

On page 67 (Section V, 2 - Nonradiating
networks), through p 71, there is much
discussion ITR. In part:

"The driving-point matrix relates the voltages
and currents at network connection points as
required by the electromagnetic interactions.
The driving-point-interaction equasions are
then solved together with the NETWORK or
transmission line equasions to obtain the
INDUCED currents and voltages."

All EZNEC seems to offer ITR, are
simple transmission line simulations where
the fed (source) energy is applied to a
segement (load).

Figure 20 (p 69) and Figure 21 (p 70)
and the related discussion, make clear that
NEC can model parallel elements coupled
through a 2-port network (simulated bi-

directional transmission line).

Since your control center appears to not
utilize 2-port networks, it is no wonder your
software fails to agree in some instances
with empirical data.

> claims you've made, rather than to show the world, at no expense to you,
> that the claims are valid. That's up to you. I'm not obligated to
> disprove your extraordinary claims.

You are, however, obligated to provide
ALL of the NEC capabilities in your
software!

If, in your closed-minded ignorance, you
wish to call critical coupling a
"pseudo-scientific" theory, so be it. But in
doing so, you leave me wondering if,
perhaps, some concepts simply lay
beyond your ability to visualize.

Chuck,

What do you need to test? What frequency(ies)?

It may be possible to arrange a test which is gratis if you are wrong and payable by a third party if you are right, in the specs:pattern/gain/SWR and so on...

Drop me an e-mail.

>to rear up?

Hi Mike,

Heavens no. There are several means to generate a clean RF source
digitally. These devices (a chip with a rock) can change phase, or
frequency in the time it takes to change a register (microseconds).
These are largely based on look-up tables feeding D/A converters.

Memory is cheap you may well know, I habitually carry a 128MB flash
drive in my pocket as my briefcase, and a 64MB voice recorder as my
stenographer, and my 32MB Palm Pilot as secretary. Grand total cost
for my "digital" office is under $300.

Another method of high purity RF source generation is direct feed of a
pulse train into amps with only the slightest of filtering. These
pulse trains are weighted to look like a binary sine wave (a few bits
on early, a lot on in the middle, and a few on in the late stage).
This work has been long available in the pages of Steve Ciarcia's
magazine "Circuit Cellar."
http://www.circellar.com/
I believe it was written up by Don Lancaster (a name that should be
resourced for ideas that approach problems obliquely). The length of
the pulse train, and the weighting of the bit positions leads to
exceptionally pure RF (spurs at least 60dB down).

The only problem here in this last method is moving that pulse train
fast enough for HF (128 bit trains to drive at HF will require you to
clock them through at UHF rates).

The only problem with the look-up/ADC method is that with my last look
at these products, they were roughly limited to 16MHz (with 0.1Hz
resolution) - so perhaps some mixing is called for at the higher
bands.

> If there is a digital mode that uses less bandwidth, sounds at least

This is why Spread Spectrum died in Ham radio. The FCC mandated we
transmit on a specific "gold code" and painted the research into an
isolated technical corner.

>I guess I hadn't looked at it from that perspective, but I agree, there
>must be some confusion as to what exactly digital is.

It is a Marketing term like fractal antenna - wholly spun from the
imagination to create the impression of advanced technology when it
has been around since the early 1800s (anyone ever here of Ada?).

The extended thin wire kernel is invoked automatically when the model is such that it's needed, according to the criteria given in the NEC manual. Two port networks are used by EZNEC only to create current sources and transmission lines.

>

I'm glad you've finally looked in the manual to correct your misconceptions about the NEC transmission line model.

> All EZNEC seems to offer ITR, are
> simple transmission line simulations where
> the fed (source) energy is applied to a
> segement (load).

In the Transmission Lines window, the user specifies which wires the two ends of the transmission line are connected to. There's no requirement that one be a "source" or one a "load". These use the NEC network model, as does NEC.

>
> Figure 20 (p 69) and Figure 21 (p 70)

Huh?

I'm always interested in hearing of any case where EZNEC disagrees significantly with NEC-2 for any model, and I'm not aware of any such cases. Anyone seeing such disagreement is encouraged to contact me. Please include both the NEC and EZNEC models.

>
> You are, however, obligated to provide
> ALL of the NEC capabilities in your

No, Chuck, I'm not obligated to do anything you say. Anyone not satisfied with the capabilities of EZNEC is encouraged to not purchase it. I guarantee that anyone who does purchase it will be satisfied.

Speaking of news articles chew on this one Chipster:

http://www.technewsworld.com/story/37378.html

So no, I'm not horribly worried about BPL running on the lines around
here. Us "Luddites" who have been proactive in the fight against BPL
have realized for a long time that it's business model is
fundamentally unworkable and that it's very likely gonna be another
dot.bomb. Like any number of the recent-era "marvelous new
technologies" which went down the pipe when the bubble popped.

Hi Brian,

From that story:
"Lastly, the commission indicated that access to BPL would facilitate the ability of electric companies to manage the power grid by delivering remote diagnosis of electrical failures."

This is one of those benefits, tarted up with a fresh paint job to convince ignorant investors of a remarkable accomplishment. In fact the industry has had this ability to perform remote diagnostics remotely for generations. The first time they sold it honestly to the investors as SCADA.

Basically, the article describes the utter failure of the FCC's ineptitude in refusing to standardize the design of the "Last Mile" connectivity. This means the mile from subscriber to the nearest terabit optical pipeline that could pump video on demand for everyone - in both directions. In other words, the best of BPL is a technological joke as a promise and bait and switch routine for an existing service that is better and closer, but fails to rise in the Neanderthalic imagination of Powell.

The "Party of Business" has been an abysmal failure as evidenced by the flat lined Dow for YEARS. The neo-cons in charge have added more layers of government bureaucracy than a frothing liberal signing laws to "help us."

## 741. 4:1 balun advice sought...

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-18 22:45:03 UTC
From: ars_wa8mea@netzero.com
Message-ID: <9ae88a70.0410181445.5fb776e@posting.google.com>
Source record: 88136

I am looking to add another type of antenna to our product line. It will require a 4:1 balun/center insulator. Because of time & labor restrictions, we would just as soon purchase another companies 4:1 balun/center insulator instead of making our own. (At least for the time being....)

It has been a long time since I've used any baluns. Seems I recall they were made by Unidilla. I see they are still around and in business. Reasonably priced, too. Is this the "best bang for your buck"???

What is the lowest priced 4:1 balun on the market? What, in your opinion, is the BEST 4:1 balun on the market???

No, I am not a troll. Just legit questions with your feedback very much appreciated.

Thanks and 73,

Bill - WA8MEA

Tom Donaly, KA6RUH wrote:
"There may be a difference in current along the coil, but it isn`t a current drop."

Call it a decline if you don`t like the word drop.

A wave traveling along an antenna induces current in the wire. This current causes radiation from the wire.

A current traveling from "a" to "b" in the wire loses energy to radiation. The energy at "b" is less than the energy at "a" if the source is at "a".

If the impedance at "a" is the same as the impedance at "b", the voltage and the current at "a" are larger than the voltage and current at "b".

We don`t need energy to decline from "a" to "b" to have a current drop. We only need current to decline between "a" and "b". Yuri has demonstrated a "current drop" with r-f ammeters inserted at both ends of the loading coil. Analysis of the cause is not necessary to demonstrate a current drop.

As straight wires are usually better radiators than the same wire in coils, I speculate that the current drop measured by Yuri is mostly due to the high impedance (High voltage, low current) on the output of the loading coil.

Best regards, Richard Harrison, KB5WZI

Check out
http://www.cnn.com/aol/story/2004/10/18/cnn_internet_wireless.city.html for an interesting story of how cities are setting up WI FI internet systems. One thing that stood out was the the consumer cost, about $30 cheaper than quotes I've seen for BPL. And it's cool that they are using existing street lamps for mounting stations.

The cities are providing a service verses utility companies providing a commodity. That means that cities are not in it for the money, unlike utility companies. Which in turn would help lower income households set up internet servies. For my situation, doing a rough cost benefit analysis, I would go with the Wi Fi System if offered. Lower costmonthly cost, better speed, less chance of interference, better realiblity (power flickered several times during a windstorm which would have meant that I would be bumped off). I could use internet for 3 months verses 1 month for BPL.

I do believe the article made a mistake in talking about interference from microwaves, cordless phones, home/business wi fi systems and baby monitors. Are baby monitors and microwaves ovensnow on 2.4 ghz? I thought baby monitors were on 49 mhz, and microwaves in the 1.7-1.8 GHZ range? The article also mentioned the low frequencies???

> Are baby monitors and microwaves ovens now on 2.4 ghz?
> I thought baby monitors were on 49 mhz, and microwaves
> in the 1.7-1.8 GHZ range?

Microwave ovens are 2.4 GHz. They do leak enough to cause interference (for example, on my 2.4 GHz wireless headphones and wireless speakers).

Baby monitors can be various frequencies including 49MHz, 900 MHz, and 2.4GHz. Can be an interesting listen once in a while.

Cordless telephones have reached 5.8GHz in addition to the other lower bands. Good ones are spread spectrum.

BTW - wait until you see Wi-Max in two or three years.

> Chuck wrote:
> > [... ]

> The extended thin wire kernel is invoked automatically when the model is
> such that it's needed, according to the criteria given in the NEC
> manual.

Which states: "Transmission lines interconnecting
parts of an antenna may be modeled either
explicitly by including the transmission wires in the
thin-wire model, OR implicitly by the method
described in the preceding section for nonradiating
networks." Then goes on to explain the implicit
model, followed by: "The implicit model is limited,
however, in that it neglects interaction between
the transmission line and its environment." (Which
is what's implied for a transmission line in the
EZNEC manual.)

When is the thin-wire model invoked?

What is your criteria for this 'automatic' choice?

Continuing: "This approximation is justified if the
currents in the line are balanced, i.e., in a log
periodic dipole antenna, and in general if the
transmission lies in an electric symmetry plane.
The balance can be upset, however, if the
transmission line is connected to an unbalanced
load or by unsymmetrical interactions. If the
unbalance is significant, the transmission line
can be modeled by including the wires in the
thin-wire model."

In the Raibeam design, the load is unbalanced
due to its "plumbers delight" construction and the
resultant matching networks. From this, one
would naturally assume the interconnecting
phasing line must be included in the thin-wire
model.

How does one determine if this is the case or
not?

Why is the user left unable to make this choice
independently?

And BTW, how does one model a receiving
antenna in EZNEC?

Re: 'video on demand' - it has been noted that one of the greatest drivers of many technologies is the p0rn industry (so I've read). Anyway...

Personally I'd be happy to write a cheque for $1k (or even $2k) to have the fibre line run all the way into my basement. $1k one-time is small potatoes as compared to $50 per month access fee (or $600 per year, NPV cash value of about $6k - YMMV).

Oh well, www.Wildblue.com is coming soon.

Followed closely by Wi-Max.

BTW - Wi-Max will put local radio broadcasters (AM/FM) in competition with Internet radio for mobile listeners (in cars). I wish them good luck <smirk>.

In any case the curve was normalized across several factors and was to be used as a guideline to substantiate that the longer the boom the higher the gain. Other factors like F/B, F/S, bandwidth, losses, etc. were not addressed.

No need. Antennas behave the same when receiving as when transmitting.
So if you know how an antenna behaves when transmitting, you also know
how it behaves when receiving.

Best regards, Richard Harrison, KB5WZI

If any EZNEC customer is interested in the answers to these or other questions about EZNEC, please email me and I'll be glad to answer them. (My only request is that before asking any question about EZNEC, you make an honest effort to find the answer in the manual. That's the only way I can possibly provide the level of support my customers deserve.)

I have the strong feeling that Chuck isn't nearly so interested in the inner workings of EZNEC as he is in simply being as big a nuisance to me as he can. After all, he's said how horrible he thinks the EZNEC interface is, and has never purchased it. And I've been guilty of encouraging his being a nuisance by responding. I apologize to the other readers for this.

I've wasted much more time with Chuck than he deserves. From here on, let Chuck, Art, Chip, and Yuri will have to vent their frustrations without me. I will continue to try to contribute positively to the newsgroup as I have (tried) in the past. Ignoring Chuck is a necessary step in doing so.

Hi, Your best bet would be to look at the archives of this group concerning baluns. A low priced, high performance, one that will work over a wide dynamic range, is very difficult. If you could narrow your design constraints, the Wireman, and Byte Mark sell some that might work.
This is an Amateur newsgroup, sounds like you are trying to make some money, if I am wrong, sorry.

Source record: 88150

What brought this to my attention was Moxon who advocated 2 element beams
(lightnes translates to greater heights) so I modeled a 20 meter beam on a 7
foot
boom and obtained 12dbi max for the band (ala< 2:1) but one can get 13dbi
if you drop the impedance from 50 to 12 ohms.
This then raised the question would a transformer cancel the increased
gain. On the F/B
question it was of real interest to me to compare the first frontal lobe
gain to the second lobe at
the rear on the basis that propagation rules the second rear lobe as the
most important .
But all of this comes to a grinding halt if there is not a datum curve to
which one can
compare ones modeling when using more than two elements on such a short
boom..
I agree that one has to model to one's specific needs and as can be seen
from the ARRL curves
using short booms max gain varies tremendously.depending on curves chosen
none of which
are the cat's whiskers such as NEC based curve.

A receiving antenna exposed to the far field, receives plane waves (essentially flat wavefront). If you 'play the film backwards', does a transmitting antenna emit plane waves?

;-)

Soooooo... ...the wavefront in the nearfield is now flat <smirk> so that it matches the flat wavefront in the receive case ?

> Reciprocity is a fundamental aspect of antenna theory.

Only if someone can explain the above discrepancy.

It seems apparent that one might arrange an array to exploit the difference between the flat (far field) incoming wavefront in the receiver mode and the obviously-curved wavefront (near field) being emitted in the transmit case to produce significantly different macro performance characteristics.

In other words, playing the film backwards doesn't work.

Does it say I am the walrus?

Hi Bob,

Obviously you've been subjected to a dumbed down attitude in response
to your question.

The fact of the matter is that the receive antenna does not sense a
flat wave approaching it because the antenna distorts the continuum
around it. The antenna and the medium out to several wavelengths is
NOT a characteristic Z of 377 Ohms as seen in an undisturbed field.
I've offered this treatment to Thierry, so it seems it would be useful
for you to observe as well at:
http://home.comcast.net/~kb7qhc/antennas/Fields/index.htm
with a specific example for a monopole at:
http://home.comcast.net/~kb7qhc/antennas/Fields/Vertical/index.htm

As you may observe, the medium surrounding the antenna is anything but
consistent. In effect, the medium and the antenna present an RF lens;
and as you may well appreciate, a lens distorts paths to optimize for
a use. This distortion is like pressing into a bowl of jello, that
medium may have been consistent in the beginning, but with the applied
pressure, the near regions to the disturbance present new surfaces and
densities. Same goes for an antenna - transmitting or receiving.

Dr. Cohen is, of course, correct.

Dr. John D. Kraus says in his 3rd edition of "Antennas" on page 439: "If an emf is applied to the terminals of antenna A and the current measured at the terminals of another antenna B, then an equal current (in both amplitude and phase) will be obtained at the terminals of antenna A if the same emf is applied to the terminals of antenna B."

>....Yuri will have to vent their frustrations
>without me.
>Roy Lewallen, W7EL

OK, we tried to have discussion about the current in loading coils, you defended W8JI position, who used EZNEC model of coil with zero physical length and "proved" that current is the same at both ends. You supported him by doing "experiment" with toroid at the bottom of antenna and writing page about how Yuri and Cecil are wrong.
We pointed out the fallacies in the way EZNEC models the coil, examples were given how to get around using hairpin or coil modeled as a "helix" by breaking turns into segments. Now this is incorporated in EZNEC 4.08 and surprise, surprise - it reflects the current distribution properly, showing that there is a difference of current in the loading coils as observed by me, measured by W9UCW, explained by W5DXP and KB5WZI. I thanked you for implementing this feature and pointed out another possible improvement in way the L is entered. The result? W8JI still keeps the crap on his web site, your letter is included there. Did we get thanks of heaven forbid apology? (You got better version, made extra bucks as result of us being "stupid") Not that I care or want to vent frustration. I mentioned before, I do ham radio as a hobby, when I see crap I try to point it out for the benefit of others.
I was going to do an article, but fortunately I have a life besides radio, had more pressing problems and this had to wait. I hope to do it soon, with some examples using EZNEC.
I wish there was more attitude here trying to discuss the problems rather than smart alec snotty attitude by some brother hams. If you screwed up or are wrong, admit it, learn, give credit where is due and we will all benefit. Nobody is perfect. But ridiculing or dumping on someone, because you (whoever) is "superior" and you "know" better, just makes that egg in the face look more yellow.

Thank you and good night!

Yuri, K3BU.us

No, although another infamous party to this thread bears a striking resemblance (including precious 'ivory towers' [tusks], thick blubber and a tough hide)...

http://images.google.com/images?q=Odobenus+rosmarus

To clarify things, lets go out 27.3 wavelengths from antenna A and mark an X. When antenna A is in receiving mode, the wavefront at X is essentially flat because antenna B is in the next county. When antenna A is in transmit mode, the wavefront at X is noticeably curved with a radius of something around 27.3 lambda. In other words, things are different even if the pathloss is the same in either direction.

I believe that it would be possible to design an antenna system (an array, a reflector system, or something with an RF lens) that took advantage of the difference between 'flat' versus 'curved' to produce an antennas system that had different pathloss in different directions (where antenna B was something simpler).

No sense arguing about it. Someone has to produce an example.

The ball is NOT in your court.

True if the antennas are reasonably close, if the signals between them have to go, propagate through the screwy atmosphere/ionosphere, then it is not necessarily true. Also, you might be transmitting one polarization and it might end up as different polarization at the other end and cause unequal current. (You can quote me on that :-)

I don`t know, but I`ve seen Yagi-Uda gain versus boomlength charts.

Before relying on such charts, it may be worthwhile to read "The Yagi-Uda Story" on page 246 of the 3rd edition of Kraus` "Antennas".

Also, the solution to a Deutsche Welle Short Wave Antenna problem on page 703 is given on page 705:

"the gain of a single 1/2-wave dipole is 2.15 dBi and of 2 collinear in=phase 1/2-wave dipoles is 3.8 dBi. The array of 8 such collinear dipoles adds 3+3+3=9 dB. The reflector screen adds 3 more and the ground bounce another 6 dB for a total gain of 3.8+9+3+6=21.8 dBi or a directivity of 151 approx."

The solved problem is worth the price of the book as a reality check.

Best regards, Richard Harrison, KB5WZI

This statement is somewhat misleading. A standing-wave antenna is
somewhat like a transmission line with standing waves. There are
TWO component currents in a standing wave antenna, forward and reflected.
The total current is the phasor sum of those two currents. Even if the
forward current were constant and the reflected current were constant,
the total current changes because of the phase shift between the
forward current phase and reflected current phase as these two phases
are changing in opposite directions.

For instance, given a 1/4WL ground plane vertical, the forward current
and reflected current are in phase at the feedpoint, thus resulting in
high current. At the tip top of the 1/4WL ground plane, the reflected
current is 180 degrees out of phase with the forward current and their
phasor sum is zero at that point.

Tom Donaly, KA6RUH wrote:
"---forget what Richard just posted."

Suits me. You recall the old story about leading a horse to water.

Tom rejects measurements of r-f currents at both ends of a loading coil at work. The currents were clearly differing.

Tom must be stuck with battereis and the rise and fall these produce in the current of an inductor.

A loading coil is usually in the antenna field in our examples. The loading coil is subject to an incident wave and to a reflected wave. These waves combine in a continuously varying phase relation along the coil to make current, impedance, and voltage all functions of their positions along the coil. Every spot along the coil is different when both waves are sensed together. That`s the way SWR works, and we`re discussing standing-wave antennas.

I have a 1982 ARRL Antenna Book. On page 13-3 there is a Fig. 6, "Improved Current Distribution Resulting From Center Loading". The loading coil clearly shows less current at its top than at its bottom.

The above extract is lost on me as I was looking for maximum gain per unit
boom length based on NEC without regard to number of elements
required to attain that gain. Thus increases or decreases from critical
coupling
can be ascertained..

> I urge any young person to read the book about jerks.

The key to understanding the total current in standing-wave antennas
is in understanding the forward current and reflected current components
and their superposition at different points along the antenna. The cosine
distribution of standing-wave current in a 1/2WL dipole is the result
of the superposition of forward-traveling current and rearward-traveling
reflected current.

An unterminated rhombic is a standing-wave antenna because the forward
current gets reflected at the open end of the wire. The forward current
causes radiation in the forward direction and the reflected current
causes radiation in the rearward direction. The radiation "loss" causes
the reflected current at the feedpoint to be a lower magnitude than
the forward current at the feedpoint. There are standing waves all
up and down an unterminated rhombic and the Vtot/Itot feedpoint impedance
depends partially upon the phase between the forward current and
reflected current and, of course, upon their magnitudes.

Properly terminating a rhombic virtually eliminates reflections and
turns the antenna into a traveling-wave antenna which radiates mostly
in the forward direction. There are virtually no standing waves on
such an antenna.

These same ideas can be applied to other standing-wave antennas, including
a 1/2WL inverted-V. In EZNEC, we can terminate the ends of such an antenna
to ground through resistors that eliminate standing waves on the antenna.
The feedpoint impedance of such an antenna is in the ballpark of 600 ohms.
Where does the low feedpoint impedance of an unterminated 1/2WL inverted-V
come from? It comes from the superposition of the forward current and
the reflected current at the feedpoint. These two components are in phase
and phasor-add to a large current. The two voltage components are 180 deg
out of phase and add to a small voltage. small-voltage/large-current is
a low feedpoint impedance. Using a minus sign for 180 degrees, the feedpoint
impedance of an inverted-V is approximately (Vf-Vr)/(If+Ir).

We can understand a standing-wave antenna by doing an analysis of a lossy
piece of transmission line. If the losses in the transmission line approximately

equal the radiation "loss" of the antenna, the feedpoint impedances will have approximately the same value.

Once standing-wave antenna currents are understood, it is easy to see why the total superposed currents at each end of a 75m Bugcatcher coil are nowhere near equal even though the forward current and reflected current at each end of the coil are close to the same value.

Circuit analysis works well when there is only one current flowing in a coil. Circuit analysis falls apart when forward and reflected currents are flowing in a coil and distributed network analysis is required when such coils are installed in standing-wave antennas.

My 1988 version shows the same thing on page 16-4, Fig. 7. Unfortunately,
two pages later, in Fig. 10 it shows how the current at the top of a
loading coil can be four times higher than would exist in an equal
top length of a 90 degree antenna. Since V*I*cos(theta) is the power, does
that mean that the voltage at the top of the coil is 1/4 the value of
an equal top length of a 90 degree antenna? So the impedance looking into
that 15 degrees of whip above the coil is 1/16 of the impedance looking
into that same 15 degrees of that same whip mounted above 75 degrees of
wire??? Doesn't sound reasonable, does it? Exactly how does that coil
manage to change the impedance looking into 15 degrees of whip by a
factor of 16 AT THE TOP OF THE COIL?????

That's exactly what happens when one uses circuit analysis on a distributed
network problem. If circuit analysis worked on such a problem, we wouldn't
need distributed network analysis.

Hi Yuri,

You fail to attribute WHO provided those "breaking turns into
segments" which was/is/isn't(?) documented at your
current/former/removed(?) page as myself and Roy. Making this a part
of the current software version is hardly the epiphany of a visitation
seeking the absolution from sin.

As I pointed out before, nothing new has been added and the fire has
been drowned in spit.

More likely so they can monitor usage so you have to get up at
3:30 am to do the laundry so business interests have daytime power to
themselves.

They'll likely also use it to shut off power for late paynment
without the nuisance of a truck roll.

Thanks to OM Mario, 9A4DE, I finally got the answers I was looking for:
Visit these sites:
1)
http://www.home.earthlink.net/~calvinf15/_technical/EH_antenna_test_repo
rt.pdf

2)
http://www.home.earthlink.net/~calvinf15/_technical/EH_antenna_test_repo
rt_2.pdf

Thanks everybody for taking part in the discussion. My dilemmas have
been solved:
- practically: I am not going to build the EH antenna.
- theoretically: The EH antenna behaves exactly according to the
existing classical antenna theory.

The plot of many individual yagis does confirm the general idea of gain being roughly proportional to boom length, and that is a very important thing to understand.

Note that this is only for long-ish yagis with many elements. For yagis of 2-3-4 elements on a short boom, the first few dB of gain come very easily. Beyond that, the data points settle back towards the long-yagi trend line.

To increase the gain by 3dB, you need to either double the boom length (and redesign the yagi, obviously) or else stack two of the same yagis... and either way, in practice you'll achieve slightly less than 3dB.

Hi Bozidar,

Looks OK until you ask yourself just what does line of sight
calibration have to do with useful DX communication? Their comparison
of AM antennas and their replacement eh model was tellingly abysmal
when it came to a practical sized service area (in other words, beyond
line of sight communications).

I notice they either suppress their FCC antenna report, or otherwise
hide their citations that offer signal reports that dive 30 dB below
the standard AM signal for their ramshackle AM replacement antenna.
A tractor couldn't bury their signal deeper.

Do you need a copy of that? I kept one in anticipation of its
embarrassing numbers (obviously misunderstood by the clients of this
test) suddenly disappearing (obviously when they finally got a clue).

You misunderstand what this curve is telling you.

There is a general law that gain is proportional to "aperture area". For something like a dish, "aperture area" is the frontal area of the dish itself (multiplied by an efficiency factor <1). For long yagis, "aperture area" is roughly proportional to boom length.

This concept has nothing whatever to do with NEC! But it is the absolute bedrock of all antenna engineering. What you really need right now is to read the first few chapters of Kraus... and understand these most basic principles.

NEC calculations will not tell you anything about this. NEC is simply a tool to calculate what the gain of a particular antenna will be (or can be, if you build it as modeled).

Well, not entirely, if he follows through the logic of what he says. An
ideal loading inductance does *not* radiate; therefore the current at
its two terminals *must* be the same.

I keep coming back to the same point: until someone correctly
understands what pure unadulterated inductance does in an antenna, he
can never *truly* understand how a real-life loading coil works.

Just about all aircraft builder supply places carry aluminum tubing as
well. I would think the 6061-T6 grade would be great for antennas as it
is quite corrosion resistant and fairly hard and thus more resistant to
bending under ice buildup if your locale supports the formation of ice ;)

Try http://www.aircraftspruce.com/menus/me/aluminum.html

Only to you Tom.

Chuck is my colleague. As I stated, that doesn't mean that I always agree with him nor that he always agrees with me. If you were not acting so mean-spirited, IMO, you would also say the same thing.

Fractal antennas are now an established and proven aspect of antenna engineering, and part of the main stream.

The only 'claims' are those in extant and pending patents.

What's next: an argument on whether SSB has any advantages over AM? Shall we bring Bill into the mix?

WiMax is a great thing, Brian. The main problem is actually one of antennas.

I think Wimax has a bright future, but I don't share your opinion that it will bury BPL. It seems more likely that it will replace Wi-Fi in extant deployments at some point. My opinion, anyway.

Hi CIL

Where lightning will hit, if it hits, can almost be calculated with a fair degree of accuracy.

We did a small project in a college class and made a scale model of a small city. We knew from past history some of the structures that were hit and where. From this knowledge we made balls of certain sizes so they would touch if sitting on the ground the place that was actually hit. We ended up with only 4 such balls, each a similar size factor to the others.

On our scale model town we outlined in red lines the most likely places lightning would hit if it did hit in that area.

Every strike since that time, up until the project was abandoned, has hit somewhere on the red lines we have drawn.
One such line was on a small single story U-Stor-It building between two very tall radio station towers, that was assumed to be lightning proof due to it's location. It was hit and hit hard when neither tower was hit. We also indicated that if those towers were ever hit, the location on those towers where the lightning would hit them. Neither location was near the top either. Two small strikes to one of the towers were both within 1 foot of where our red line was indicated on the scale model.

We were so successful in our project we thought for sure some agency would pick it up and make use of it. But long after I was at school there, the project was abandoned with something like a record of 94% accuracy on pinpointing areas where lightning can hit.

Oh dear, my generalisations have yet again confused those of electronics
academia and has caused interpretation problems with a gargantuan
proportion.

Maybe my sentence " You know what the trouble is with us amateurs is? "
should
be changed to " You know what the trouble is with all those on this list is:
" ( followed by a list of every amateur in the world , but filtering out
those who don't reply to an extensive survey to find out if they would like
to be included in the generalisation "we". )

He casts... he waits... ( not long ) , and he reels them in...

CIL wrote:
"---is there anything I can do to fix this?"

Broadcasters have towers that are often struck by lightning. AM towers sit on base insulators which makes them vulnerable to static buildup too. Wind carries a static charge which falls out on the tower even when no lightning is present.

The shape and positions of charged clouds are constantly changing, so lightning strikes can come from anywhere.

The broadcaster starts his lightning protection at the tower top with a small lightning rod extending above and beyond the beacon to take the hit and avoid expensive repairs at the tower top.

Tower guy insulators are doubled and tripled where they connect to the tower so that static breakdown occurs to the earth instead of at the tower.

An air gap is installed across the base insulator to bypass a lightning hit to earth. Often a turn or two is made in the feed to the tower. This discourages lightning on the feedline and encourages breakdown of the gap across the insulator.

A static drain choke is often added if needed to provide a d-c path between the tower and the earth. It is used to bleed off charge which might build to dangerous levels.

"Lightning elimination" is a name given to mounting a large number of sharp points around a protected area in an attempt to drain the atmosphere of charge. The reviews are mixed.

I`ve worked in several broadcast stations hit by lightning nearly every time a charged cloud passed by. None ever caused significant damage. Al of the stations had lighted towers but their tower lighting chokes kept lightning off the a-c power source.

Berst regards, Richard Harrison, KB5WZI

What's to research? Just cut two 45' lenghts of wire,
string it up as a dipole & trim for resonance. Easy.

BTW you should hear how good WWV (5mhz) comes
in on such an antenna. Nice.

|gain from an antenna other than boom length and number of elements.
|
|ie On 2m we are able to get 11.2 dBd on a 45inch boom with 3 elements
|stacked 2 wide. Yes, this is range tested see results at
|http://www.csvhfs.org/ant/CSANT04.HTML

Uh Oh! The measured data show 11.2 dBd, the advertising shows 13.97
dBd. I thought maybe I went to the Raibeam site by mistake but no, I
went here:

http://www.degendesigns.com/StackedVwave.htm

I love that precision BTW. I've done a fair amount of antenna range
testing using HP 8510s for measurement receivers and I've never been
able to establish gain within 1/100 dB.

But you can do it with a ham receiver and "subjective analysis".
Congratulations.

Since you're using two 45" booms spaced 58" apart, I would argue that
you should compare your design to a 148" boom Yagi and see what
happens.

How about posting your dimensions so we can see what modeling says
about them.

One further note: The Dataq DI-194 mentioned at:

http://www.degendesigns.com/Downloads.htm

WILL NOT work with all computers. This device is powered by the
serial port and my Toshiba laptops will not drive it.

Why should I? You wouldn't believe me anyway since you and Richard are wedded to your own fractured version of electromagnetics. Besides, Tom Rauch does a good enough job on his web page.

Ian White, G3SEK wrote:
"An ideal loading inductance does "not" radiate."

A loading coil does not need to radiate to produce significant difference between the current at its ends.

The same power may be produced at various impedances. The product of the real voltage and the real current must be the same in all cases for the same power.

A loading coil experiences a different voltage to current ratio (impedance) at every point along its length.. This is due to the combination of forward and reflected volts and amps. Because of the reflection, their forward and reflected vectors are rotating in oposite directions. This makes every spot along the paths of these vectors unique with its own voltage to current ratio (impedance).

Cecil. W5DXP has already posted in some detail how the forward and reflected values encounter the incident values and their superposition produces a new impedance. That surely happens at the load end of a loading coil.

If the phase between the incident and reflected waves, at the coil to whip junction, makes a different impedance than that at the feed end of the coil, it is likely that the coil output current will be different from the coil input current That`s expected.

Best regards, Richard Harrison, KB5WZI.

## 812. Re: Gain per unit length of boom

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-19 16:15:22 UTC
From: "aunwin@insightbb.com"
Message-ID: <t4bdd.277152$D%.236528@attbi_s51>
Source record: 88107

Ian, All the points you made are very good especialy when you
stated that gain is ROUGHLY proportional to boom length and
then go on to mention "aperture'
The question I asked was very specific but not personal like the
presidential
debates this newsgroup uses the question as the basis for what they want to
say.
The reason I asked the specific question was to obtain a datum line for
antennas relative to gain and a well used term of boom length.
NEC programs can provide this basic if the latest revision is used
and the program is all encombassing.( Many are not)
Mention coupling and some experts go nuts
but NEC is all encompassing provides definitive answers that remove
measurement errors presently shown and cuts through a lot of garbage.
All encompassing is all important in that sufficient segments are available
together with the use of variuable dimensions as this gets away from use of
methods
to get around inadequacy of a particular program. You mention "aperture"
but I don.t believe it changes any results given by NEC. Others ridicule the
use of the term
critical coupling yet NEC shows that element currents can be changed via
coupling
and it is current placement that we are interested in, so why so much
redicule/
The same goes for element diameters NEC provides the correct construction
for
elements which is another important variable for gain
So in other words, a NEC curve would deflect most arguments and personal
agenders
from the beginning and if one supplies actual measurement that are contrary
to those of NEC
then we have a basis for truly specific debate. As somebody pointed out, one
slanging match
has been going on for more than eight years regarding the use of critical
coupling, another is
the subject of coils, actual measurement versus a manipulated program
calculation.
I pretty much have had it with excuses regarding inadequecies of some
programs,
If NEC is a really viable tool; then let us use it as a datum by using a NEC
program that
is all encompassing to judge measured claims against so hat true specific
can be judged.
It is possible after all that even NEC may obtain several more revisions

over time because of
actual measurement which can only aid all in the understanding of antennas
and the removal
of old wifes tales and private agendas that evolved prior to NEC.
Is it auguments that we yearn for on this newsgroup or true resolution of
ideas?
Art

You're right about the understanding part Ian, but Yuri is trying to
make generalizations based
on the measured behavior of real coils without taking too much time
to analyze why the behavior of his coils departs from the ideal.
Making up terms, such as "current drop" to give more technical
credence to his ideas doesn't help. Richard's attempt to justify
Yuri's technical jargon is little more than pathetic.

need help understanding what is wrong with the reception of one channel. i have an old metal antenna on the house that works great for the strong local signals. years ago i added a small antenna that was designed to pull in one particular local channel. it is installed on the same pole, and plugs into a small box also on the pole that acts as a splitter i guess. anyway, regardless of whether i am running the signal into the vcr or the tv, all the powerful channels come in fine. however, this other one, channel 13 (Hmmm...) doesn't come in well unless i disconnect the coax from the tv, then very gently touch it to the connection on the back of the tv. the improvement is dramatic, but i'll be damned if i'm gonna watch tv this way. i don't understand why the same connection works great for the other channels, but not for this one. i have tried changing out the cable, using splitters, not using splitter, directly from wall, from vcr, etc. it never seems to come in unless i am holding the cable connection to the connector on the tv in this very specific way. what's going on? i know this station used to come in better, but now its crap. help. anyone?

Can you describe how each tower was configured at the top and how it was grounded?
What is important to know if the top ended up with sharp point (mast, VHF vertical antenna, etc.) or Yagi type antenna, like tribander etc. without anything pointy protruding above.

Yuri, K3BU

## 816. Re: Is lighting nuts?

Source record: 88111

I would suspect a poor grounding system on the tower. If the ground is a rod driven into the Earth, then the impedance needs to be as low as possible. Once the ground system takes a surge, glass crystalls will form in the dirt on and around the rod. The impedance then climbs and the number of strikes to the tower increase. The amount of impedance in your ground network determines the amount of static charge that can build on the tower and how fast the charge can bleed. The formula for calculating the bleed rate is 5 times (Resistance times Capacitance). The resistance is the ground impedance and the capacitance is the amount of surface area of the tower relative to the air flow over it (think of two plates on a capacitor with a dielectric between them). Any charge above that of the Earth makes that point more likely to get hit by lightning. The tower is only one item to concern yourself about because a floating antenna can be just as bad. Ground everything on the tower during a storm if it is not in operation such as a repeater. Surge arrestors on the antenna feeds then become imparative for repeater installations. A very large grounding system is required to mitigate the potential for lightning strikes on a tower. If a strike does occur, then the grounding structure needs to be able to dissipate the charge back into the Earth very quickly or the ground will be lost until the voltage on the ground falls. Again, R x C for the Earth.

Good Luck,
Frank N1SIF

Slight difference. Rauchians choose their words as weapons of smart ass attitude at "morons" who happen to be right, while Rs are wrong. They fail at the discussion of facts and arguments. I resort to (not too proud of it) responding and biting back in order to prove the point. There is reciprocity but not ideal, just like RF current behavior in real coil.
And he did it for the fifth time, go figure. Fuggetaboutit!

Wes,
You make the point quite well that I was trying to make before I read your post (written simultainiously)
and at the present time NEC is seen as judge absolute.
Yes there are many ways to increase gain but you cannot use a shackled NEC program to authenticate
the results and we often use such as a crutch.
On the subject of boom length
I was basing things on a single boom length where number, position and physical atributes of additionion elements
are brought into play to overcome program idequacies and provide correction of assigned dimensions to achieve maximum gain.(Is this to much to ask now that we have the NEC tool/)
To often the accusation comes up that computor input was incorrect or not enough segments provided e.t.c.
and a datum curve would prove a valuable tool, not only to those that use computor modelling but also
to experimentors who seek real world answers and possibly challenge the authenticicity of either methods
Thanks for the links,will read them later, have to get a flooooo shot now

Of course, Richard, but the NEC manual says
it is capable, so I was wondering why this
function wasn't included in the EZNEC control
panel, since Roy is claiming his software is
a fully functional NEC application.

Hi OM,

When you are holding the cable in its odd way (and it works just
fine), then you have happened upon an unique combination that proves
you should be able to do it right. However, the question remains,
what are you doing wrong?

Is the new antenna pointed in the right direction? Try turning it
through all 360ï¿½ to see how that improves/degrades the situation.
This presumes you have all the right connections of course.

As you are using two antennas, how are you connecting them to the same
TV or VCR? As you have tried this antenna individually and still
found no happy conclusion, it would seem to be an elemental problem.

How far away is this station you are trying to get?

What kind of neighborhood are you in (city/suburb/rural)?

Are there path issues like hills?

Is this a matter of a snowy picture, or one that is broken up with
multiple images, or...?

What kind of line are you using? Twin lead (flat ribbon) or Coax
(round, thick cable)?

Although you've provided a good bit of detail, some questions still arise: just 'how' do you "touch the coax to the connection?" Are you touching just the inner conductor to the outside of the connector, or the inner conductor to the inner connection on the connector (not allowing the ground to make contact)? Are you touching the coax connector on the TV at all...perhaps instead the 300 ohm (if any) connectors?

Without being a bit more specific, I doubt anyone's going to be able to help you. For one thing, I don't understand how the two antennas are connected on the pole in such a manner as to preclude interaction (perhaps a ch. 13 trap in series with the 'all channel' antenna before the splitter/combiner?).

In any case, your problem is probably 'up the pole.' If it worked before, i t should work now; unless conditions have changed. Have any tall buildings been constructed between you and the transmitter?

My best advice would be to have the same people who installed the array (or other competant service people) service it. It sounds like your technical knowledge is limited, and I doubt you're going to want to climb that pole...

...or get cable.

jak

Good grief, Roy...

I asked honest and valid questions,
seeking honest and valid answers.
Instead, I get this pejorative, and rather
disingenuous diatribe.

My obtaining a legal copy of your
software - with your full knowledge, I
might add - was for evaluation purposes
only. It is common opinion, that your
DOS interface was less then desirable.

Considering this highly unusual reaction
to my questions, It's not unreasonable
for me to now assume that you left out
the thin-wire model. Surely you weren't
thinking it was superfluous and no one
would really need to use it. Perhaps you
were just concerned about speed and
memory back in the days of the 80386.

* [p 72, NEC2d documentation] "The
* explicit transmission line model is, of
* course, less efficient in computer time

* and storage because of the additional
* segments required."

I have for a long time, suspected there
was a tx line modeling problem in NEC.
Now, it is apparent this problem exists
only in your EZNEC.

Tort liabilities aside (that's not my
concern here) let me suggest that it
may be in your best interest to address
this issue, not covertly as you seem to
be suggesting, but openly, in a way that
will illuminate your honesty and integrity.

How eloquently formulated and true. Xcuse my sloppynessss. You and W4RNL showed when coil is modeled as wire running around in circles with reasonable segmentation, the current is modeled very close to reality - different at both ends and not equal. Anybody can verify that with HELIX feature in EZNEC 4.08.

Actually there is another cudo to you for the treatment of space impedance and interaction with antenna impedance. I have questioned that way back and was shut off as ridiculous (Roy?). Your color pictures are very illustrative.

Another "silly me" try at using term of "electrical length of conductor or antenna element" vs. physical, was poo-poohed by Roy - no such thing in textbooks. Regardles, I keep using it, makes sense, especially with insulated wires and oddball conductors.

I apologize for not doing the promised article, life has been just too much here, but I keep hoping for better days and nicer weather. We have acquired lovely beachfront QTH at the Jersey shore, across the bay with potential of having superb antenna test field. This is next to 170 acre Rhombic antenna farm. Looking forward to fooling around with some crazy things.

Those two paragraphs, one right after the other, say it all. You want to gallop straight on to talk about "loading coils".

I want you to stop and think a moment, about how an IDEAL INDUCTANCE behaves in an antenna. (Sorry to shout, but every time I type "ideal inductance" quietly, you seem to read something else :-)

Hopefully you will agree that an IDEAL INDUCTANCE does not ever have different currents at its two terminals, and does not radiate either.

Hi Chuck,

You asked how to avoid this (if indeed it exists), and I offered a very simple response to which you have had no comment. You continue this "claim" of a problem and yet with very simple modeling alternatives to prove it (aside from testimonials) you have yet to achieve this proof or demonstrate you have even attempted a resolution. Is this because it is not in your interest?

Roy has offered a means to have a third party verify your claims, independent of his software such that it comes down to you are right, or he is right. You have not taken this offer either and it seems, given the expense, you either cannot afford to be right (which would be fully funded by Roy) or you cannot afford to be wrong (which would be fully funded by you). Any "expense" grievance leans towards the second interpretation.

You also had another offer to range test, but I can full well appreciate your backing off from that in overdrive. Any such offers should be closely attended by "Who owns the intellectual rights to the results?" If you claimed X gain and the test demonstrated X+1 results because of "simple adjustments" at the site, "Who owns the intellectual rights to the results AND the "new" antenna?" If you attempted to publish the results (assuming they were complementary) would you be threatened with plagiarism and copyright violation?

Answers to these questions may be researched at the Google Archives by simply entering the search terms of "Patent Pending," "you may be sued," "my lawyer will contact your lawyer," "intellectual property." Once you use any one of these phrases (or all of them - it constitutes one of our best Soap Operas), simply sort on the basis of author hits to see who holds the record for these issues as a business manifesto.

It won't be Roy.

There seem to be solutions in the queue, what remains to be seen is if one or several are visited, or if future communication will be stuck in the groove of repetition and denial.

This is the Rauchian difference.

I will agree in this respect, but not all Toms are Rauchs. The term
"Current Drop" is abhorrent to some (a pollution of technical
language), an irritant to others, and inconsequential to many who
simply enjoy the cat fight.

I can take only so much of the technical pollution. The breaking
point for me is when foreign terms are elevated to prayer status and
made icons of a new theory. This, for you, I presume constitutes much
the same issue as
>They fail at the discussion of facts and arguments.
which you are closely mimicking in the tedious and insistent manner of
upholding a foreign usage. You agreed that Tom (Rauch) could have as
easily chosen better language, the same resolution is afforded in this
current contretemps too.

A simpler resolution is to simply drop it and move on.

As far as I'm concerned, the results are for Chuck to do what he wants with;
I'm just volunteering time, range, and equipment.

And, if Mr. Lewallen wants a proxy, he can get his colleague Steve Best to come
down. Steve works about 1/2 mile from here.

Of course, should Chuck's results be compatible with his specs, then it seems
that a third party must pay the bill.

That sure seems fair to me.

No one is frustrated, as far as I am aware of.

Why are you trying to create problems that don't exist, Mr. Clarke?

Ian White, G3SEK wrote:
> An
> ideal loading inductance does *not* radiate; therefore the current at
> its two terminals *must* be the same.

This is misleading. Since virtually all coil-loaded mobile antennas
are *STANDING WAVE* antennas, there are two current components which
superpose to your total current. Let's assume a certain loading coil
does not radiate. The forward current is the same magnitude at the
bottom of the coil and at the top of the coil. The reflected current
is the same at the bottom of the coil and at the top of the coil.
There is a phase shift through the coil that affects both those
currents. The total current is the phasor sum of the forward current
and reflected currents. That phasor sum is different at the bottom
of the coil and at the top of the coil. The constant current principle
definitely applies but there are two component currents with phase
shifts to worry about, just as there are in a transmission line with
reflections.

Do you use circuit analysis on a transmission line with reflections?
If not, why do you use circuit analysis on an antenna with reflections?

> I keep coming back to the same point: until someone correctly
> understands what pure unadulterated inductance does in an antenna, he
> can never *truly* understand how a real-life loading coil works.

Ian, using circuit analysis on a standing-wave antenna is not valid.
Until someone correctly understands that only a distributed network
analysis works on a standing-wave antenna, he can never *truly* understand
how a real-life loading coil works. Hint: When installed in a standing-
wave antenna, a loading coil works like a transmission line so circuit
analysis is an invalid approach. The cosine current distribution on a
1/2WL standing-wave antenna is just 180 degrees of a standing current
wave which necessarily must possess two superposed current components,
forward and reflected.

This is just another example of an invalid math model trying to
dictate reality instead of reality dictating a valid math model.

Until someone understands the nature of forward current and reflected
current on standing-wave antennas, one will remain confused and be
tempted to use that invalid circuit model.

Your circuit model can be used on traveling-wave antennas. It is NOT
valid for standing-wave antennas.

Source record: 88030

Hi Wes,

Yes I am aware of the difference between the advertising on the site and the range results.

As you are aware antennas do not have even gain across the entire band. We have designed the antenna to cover the entire 2m band and as a result do see a variation in the perfromance across the band, hence max gain.

And before you cut down my comments, the precision on the results are from the softare and we are in the process of redesigning the format to more accurately reflect our actual results both modelled and actual. Unfortunately our business is antennas and web design.

The results posted on the CSVHF society are valid as the antenna was tested with a gain of 11.2dBd at 144.18MHz Horiz Polarization. Design Freq is 146.0MHz.

We are in the business of designing and selling antennas not developing antennas and giving them away for free. However, if your serious about the data for the antenna contact me directly so that we can discuss the details (email listed below).

As to the DATAQ, well I have no answer for that one, as we don't build it or sell it. Our software is designed to with run it. Strange though, my Toshiba does and so does my SONY through a USB to SERIAL converter.

One final point, the purpose of the posting was that identify that an antenna does not always need boom length and elements for gain and that there are other ways to achieve this.

Respectfully,

Guenther VE3CVS

> Yuri's technical jargon is little more than pathetic.

There doesn't need to be a current drop through a coil for the
total current to be different at each end. Assume a base-loaded
mobile system. Assume the forward current through the coil is
constant at 1.1 amp. Assume the reflected current through the coil
is constant at 1.0 amp. Assume the phase shift through the coil is
45 degrees.

If the forward current and reflected current are in phase at the
base of the coil (feedpoint) the total current will be

1.1+1.0 = 2.1 amps of total current at the base of the coil.

The total current at the top of the coil will be

1.1 amps at -45 degrees superposed with 1.0 amps at +45 degrees.

1.1*cos(-45) + 1.0*cos(45) = 1.48 amps.

The coil is lossless and the component currents are absolutely
constant through the coil yet the superposed total current at
the top of the coil is only about 71% of the superposed total
current at the bottom of the coil. No "technical jargon" involved.

Using circuit analysis on a distributed network problem simply
demonstrates ignorance of the problem. It's an easy mistake to
make and a hard mistake to admit.

A graph from NEC data is going to be pretty much like a graph from the ARRL books. By putting the data in a graphic form your are placing the same limits on the data as they had to in the ARRL books. The ARRL graphs give you a pretty good idea of what goes on when you change element spacing, number of elements and so on. What they dont do is alllow you to perform optimization like the NEC programs . Graphing a NEC program output would be the same as going back to the time all you had was the graphs to go by unless you are willing to do all the calculations on your slide rule or calculator. What I am saying is that you already have this data. No point in reinventing the wheel.Unless you think yiou can get a patent on it.

Thanks! Yes, I am trying to keep up with all the new stuff, plus some older, I have been out of main stream circuit design for a while, but looks like the timing is just like back then on the trehshold between sparks and tubes. One think that our dual channel DSPed RX will allow is to stear the antenna patterns and some far out noise elimination and processing.

We have standing invitation to the brightest minds among hams to contribute or participate in the Dream Radio One project. www.computeradio.us

> behaves in an antenna. (Sorry to shout, but every time I type "ideal
> inductance" quietly, you seem to read something else :-)

Ian, please take your own advice. It's pretty obvious that you are thinking about an IDEAL INDUCTANCE in terms of a lumped circuit analysis which is invalid when analyzing a STANDING-WAVE ANTENNA. The equations governing the behavior of a standing-wave antenna are similar to the equations governing the behavior of a lossy transmission line with reflections. In fact, just by looking at the equations, you cannot tell whether they apply to a transmission line with reflections or to a standing-wave antenna.

Hint1: Write the equation for the total current on a standing-wave antenna that includes forward and reflected currents and "loss" due to radiation.

Hint2: A real-world mobile loading coil acts like a section of transmission line where Z0=SQRT(L*C). It does NOT act like a lumped circuit inductance.

Hint3: An IDEAL INDUCTANCE doesn't exist in reality. Lumped circuit inductances are a shortcut that doesn't exist in reality and surely does NOT apply to distributed networks like a standing-wave antenna.

> Hopefully you will agree that an IDEAL INDUCTANCE does not ever have
> different currents at its two terminals, and does not radiate either.

Can't agree to that at all. In fact, here's a repeat from another posting that proves that the superposed forward and reflected currents at each end of a lossless inductance *cannot* be equal. Please don't use the copout excuse that an ideal lumped inductance doesn't have any phase shift through it. *ALL* real-world loading coils have a phase shift that can easily be measured. If it has any phase shift at all, the current magnitudes at each end of the coil *cannot* be equal unless a current min/max occurs in the middle of the coil which doesn't happen in a typical mobile antenna.

P.S. How about discussing the technical issues instead of the personalities involved?

There doesn't need to be a current drop through a coil for the total current to be different at each end. Assume a base-loaded mobile system. Assume the forward current through the coil is constant at 1.1 amp. Assume the reflected current through the coil is constant at 1.0 amp. Assume the phase shift through the coil is 45 degrees.

If the forward current and reflected current are in phase at the
base of the coil (feedpoint) the total current will be

1.1+1.0 = 2.1 amps of total current at the base of the coil.

The total current at the top of the coil will be

1.1 amps at -45 degrees superposed with 1.0 amps at +45 degrees.

1.1*cos(-45) + 1.0*cos(45) = 1.48 amps.

The coil is lossless and the component currents are absolutely
constant through the coil yet the superposed total current at
the top of the coil is only about 71% of the superposed total
current at the bottom of the coil. No "technical jargon" involved.

Using circuit analysis on a distributed network problem simply
demonstrates ignorance of the problem. It's an easy mistake to
make and a hard mistake to admit (especially for gurus :-).

There is no direct connection between boom length and gain. This is because
lengthing the boom also implies one has added elements and possibly made
adjustments to element spacing. A good source of the data you seek may be an
antenna catalog(or manufacturers web site). compare the published gains of
the different length antennas.

Heh, heh, so you don't believe there is a current drop between the current maximum point and current minimum point on a transmission line with reflections? Seems to me going from 2 amps at a current maximum to 0.1 amps at a current minimum is a measurable drop in total current.

Would you please provide a proof that going from 2 amps to 0.1 amps is NOT a drop in total current?

Just one more example of trying to use lumped circuit analysis methods on distributed network problems. Are you guys ever going to learn?

Hint: With distributed networks involving an appreciable percentage of a wavelength, there are definitely current drops in the series loop. This certainly applies to 75m Bugcatcher coils used on standing-wave mobile antennas.

Sorry, the previous message went out only partially. Here is the whole:

Thanks to OM Mario, 9A4DE I finally got the answers I was looking for.
Visit these two sites:
1)
http://www.home.earthlink.net/~calvinf15/_technical/EH_antenna_test_repo
rt.pdf
2)
http://www.home.earthlink.net/~calvinf15/_technical/EH_antenna_test_repo
rt_2.pdf

That means:
- practically: I am not going to build the EH antenna;
- theoreticallay: The EH antenna behaves exactly according to the
classical antenna theory.
Thanks everyone for taking part in the discusson.

Ian, G3SEK wrote:
"Hopefully you will agree that an IDEAL INDUCTANCE does not ever have different currents at its two terminals and does not radiate either."

Sorry to disappoint you, but adequate demonstration has already shown different currents in and out of a loading coil. I won`t claim it was an ideal inductor.

The title: Re:Current in loading coil. EZNEC- helix. This is not about an ideal inductance.

An inductor, inductance, or retardation coil is used to provide inductance.

An inductor has a second definition:
"A passive fluidic element which because of fluid inertness, has a pressure drop that leads flow by essentially 90-degrees." Sounds vaguely familiar.

Inductance is defined as a "property of a circuit that tends to oppose any change because of a magnetic field associated with the current itself. Whenever an electric current changes its value, rises or falls, in a circuit, its associated magnetic field changes, and when this links with the conductor itself an emf is induced which tends to oppose the original current change."

If the purpose is to provide inductance, and the purpose of thiis inductance is to exhibit Lenz`s law, then an ideal inductor does not radiate, but I`m not convinced it does not have different currents at its two ends, as this says nothing about the coil`s quality or perfection.

After all, self inductance is the production of an oppositely directed current in reaction to an imposed current.

An ideal coil can very well be arranged not to radiate or couple to the outside world other than through its terminals. These terminals can face very different impedances depending on where each is connected in a circuit with standing waves. That is what confronts the ordinary loading coil in an antenna circuit.

Best regards, Richard Harrison, KB5WZI

Sorry for the spelling error crystalls should be crystals. When lightning hits the Earth, the heat it generates is enough to make glass which is an insulator. The ground rod becomes isolated from the Earth. If you spread out the contact area with the Earth as with the fence around the perimeter of the property, then the energy is not concentrated to one spot. The over all impedance is also much lower. I would install a ring grounding system around the tower. A 32ft. diameter ring would do nicely in a clay/rocky soil. Place 8ft. ground rods in the ground every 16 ft along the 32 ft. diameter circle (approx. 6 rods). Each rod is then connected to the tower base with a multistrand 00 copper wire and a ring of 00 copper to connect each rod together. The connections should be cad welded or at least treated with a deoxit coating to prevent corrosion. I have had excellent luck with this approach, no lightning hits and my tower sits up at 870ft. ASL or 650 ft. above average terrain. Note: the tower has a strike counter hooked up to it so I know no hits have happened. Go to this link to read more http://www.polyphaser.com/ppc_pen_home.asp .

Ever wonder why everyone is ignoring the 180 degree phase-reversing
coils described by Kraus in _Antennas_for_all_Applications_? Real-
world coils change the phase of the current from end to end. That
real-world phase shift is all that is required for the total current
at each end of the coil to be different when installed in a standing-wave
antenna undergoing superposition of the forward and reflected currents.

What we seem to have here is a bunch of gurus who are incapable of
admitting that they mistakenly used the lumped circuit model when
they should have used the distributed network model. It's an easy
mistake to make and a hard mistake to admit.

What, Coililng the wire has nothing to do with how well it does or does not radiate, only with how the radiation is summed into the total field. The current distribution in a loading coil should be very similar to the current distribution in the secton of antenna it is replacing.

Hi Richard,

To be blunt, I didn't see any merit in your
suggestion. (1) there are no modeling
alternatives for this problem, and (2) it
failed to address the issue: Roy's apparent
omission of the thin-wire model in his EZNEC,
which he touts as a complete NEC application.

I suggest you re-read the posts if you truly
are interested, then read the NEC2d
documentation to confirm. As far as
independent empirical testing is concerned,
there is nothing new to be learned other than
revealing EZNEC's shortcomings in this
regard.

> Roy has offered a means to have a third party verify your claims,
> independent of his software such that it comes down to you are right,
> or he is right. You have not taken this offer

I accepted Roy's offer, but with conditions. So
far, he has declined to accept those conditions.

I did accept Chip's offer, though.

IRT your other oratory ramblings: Incoherent
nonsense...

Actually, coiling the wire tends to reduce the far-field radiation
because much of the near-field(s) cancel each other. The currents
on each side of the coil are traveling the opposite direction in
much the same way they do in a transmission line. However, that
doesn't mean the currents at the bottom and top of the coil are
identical. The magnitude of the total current at the bottom and
top of the coil depends in large amount on the phase shift through
the coil.

We used to call em "johnny balls" at the base of the AM towers. One station I was chief engineer of was hit constantly without any damage. NOT fun to be in the transmitter room when lightning was hitting tho! I felt like Dr. Frankenstein in my lab during the storms, when I had to go into the xmitter room.

A static drain choke is an EXCELLENT idea, I have used it on my ham antennas in the past.

Gary, there is no nice way to say this, but I mean no disrespect to your experience. Unfortunately, what you wrote is absolutely incorrect, and flies in the face of thousands of lightning experts all over the world, who agree only that a 300' sphere rolled over a surface will indicate (by touching) the most likely points of attachment. This means that no taller object escapes the likelihood of being a point of attachment, period. It doesn't mean anything below it is free from side attachments and flashovers. Everything else you followed with was erroneous, based on misconceptions or complete falsehoods. Places you think lightning "struck", were more likely the opposite, the point(s) where it *left* a structure.

Every once and awhile a new theory arrives claiming to predict or prevent lightning, and these have all been discredited, especially the CTS (Charge Transfer System) of lightning dissipators. There have been and there is no evidence whatsover that a point of attachment can be either predicted or prevented. This is even when the best lightning air terminal is in place at the highest point on a structure. Take your old notes and paper the bird cage, they offer only false predictions that cannot be replicated or withstand the studies that have tried this a hundred similar ways.

You have left at your disposal, the ability to make it as easy as possible for a lightning attachment or near field effect from same, to be absorbed and routed via capable grounding and surge protection systems. There is nothing else newsworthy about it.

CIL wrote:
"What do you call these chokes?"

Tower lighting chokes. Every a-c power wire on most AM broadcast towers is fed through through a high-current r-f choke, beacon, side lights, and neutral. It avoids shorting out the tower at its base for the r-f signal.

Another device is used at some stations for the same purpose. It is called an Austin transformer and consists linked loops to transfer a-c power while providing little r-f coupling.

Tower lighting chokes must provide better performance for the price because they seem more prevalent. Tower lighting chokes may all be wraped around one form or on separate forms. They not only provide good r-f isolation, but they provide almost complete lightning isolation. They really keep lightning out of the a-c power circuits on the ground when used with appropriate bypass capacitors and arresters.

Best regards, Richard Harrison, KB5WZI

Yep:-) Sure did. I posed no conditions nor restrictions for Chuck. It's his antenna and his technology. I don't have any bias on how or why it works; I'll just measure it. Period.

I will have no problems testing it with a professional outdoor range setup.

No 's' meters here, friends.

If a third party has offered to pay for the tests if they meet Chuck's extant specs, that's fine with me. In fact, my inclination at this point is to have that third party pay up directly to Chuck. I'm happy to do this for Chuck, gratis.

Chuck can do what he wants with the data.
Always happy to help a colleague.

73,
Chip N1IR

Next, Cecil, you're going to be talking about a "current gradient"
and a "scalar current field." Here's a question for you, Cecil, and
Richard Harrison, and Yuri, too: how do you take the gradient of
the current at a point on a transmission line, and, if were possible
to do so, what is the physical significance of the result?

Sigh.

It's really a shame that I have to keep returning to this bashing session just to correct the false statements about EZNEC that Chuck keeps inventing. He did, at least, give the thread an honest and appropriate name. Responding only to his mistruths:

Chuck wrote:

> To be blunt, I didn't see any merit in your
> suggestion. (1) there are no modeling
> alternatives for this problem, and (2) it
> failed to address the issue: Roy's apparent
> omission of the thin-wire model in his EZNEC,

I clearly stated in an earlier posting that EZNEC implements the extended thick-wire kernel as required by the model. (The thin-wire kernel is the default.) Chuck has chosen to either disbelieve or ignore this, although I have no idea why he even cares about EZNEC's inner workings. Once again, I welcome any example of disagreement between EZNEC and NEC-2 modeling results. (Those which have been submitted in the past have nearly always been the result of the models indavertently being different, the most common error being due to the use of wire radius in NEC-2 and diameter in EZNEC.)

> which he touts as a complete NEC application.

I have never, at any time, claimed that EZNEC does or would implement all the features of NEC-2, so Chuck will never be able to support his fabrication. The lack of "patches" in EZNEC is in itself a difference that's obvious to anyone with even a superficial acquaintance with NEC-2. What I do claim is that EZNEC uses NEC-2 for the calculations it performs, and that the results one gets from EZNEC will be essentially identical to NEC-2 results.

EZNEC does have many features not present in NEC-2.

I don't know what's motivating Chuck to continue making false statements about EZNEC, but I caution readers to look at the record, archives, or other sources of information before believing what he says. You can't say you weren't warned -- just look at the thread subject.

Come on Jimmy,' pretty much like' doesn't cut it on this newsgroup or in any
of the professions
The same as pretty close is not accepted when doing math at college.
The curves in the ARRL book were done on 'standard' yagis
measured in the field, at least two of the curves therefore have measuring
errors, and possibly
three of those do not match NEC formulated curves.
Since you do not want to reinvent the wheel which curve or formula do YOU
want all to
follow for short boom antennas i.e. which curve, and there are many,
represents the "wheel" .
that can be specifically used as the datum curve in response to my specific
request?

Note, a NEC produced gragh will produce a scattering of points for
different yagi's
but only ONE point for MAX GAIN PER UNIT LENGTH OF BOOM regardless of how
many elements are used which when used on short booms produce coupling
effects which
change current flow, an effect not generally seen when elements are not
critically coupled
as in the standard yagi..

Thus the reason I was specific in my request which should have
removed comments such as 'Patents" from those who seek arguments .

Art

By putting the data in a graphic form your are placing the same

It makes life easier to compartmentalize your scientific world-view in that way.... but it is deeply, fundamentally wrong.

In reality, all true scientific knowledge joins up seamlessly - that's how we *know* it's true! If we can't see how it joins up, that means we still have work to do. Dividing it into compartments that don't join up is lazy and will always lead you false.

A fundamental physical property like inductance doesn't change its behaviour depending on the situation it finds itself in. If you cut the antenna wire and insert an ideal, lumped inductance, that inductance will behave in exactly the same way as it does in any other circuit.

If you really looked hard at the math of antennas considered as transmission lines, you would find there is no problem whatever about inserting an ideal inductance, with no difference in current between its two terminals.

Sorry, I should have said that boom length is roughly proportional to
the *available* gain, if the whole length of the boom is populated with
elements in such a manner as to optimize the gain. That requirement is
usually taken as understood.

Hi Art,

Can we assume this gain was calculated
at a particular height over ground?
Personally, I prefer FS results, in order to
eliminate any ambiguity.

> but one can get 13dbi
> if you drop the impedance from 50 to 12 ohms.
> This then raised the question would a transformer cancel the increased
> gain.

Optimizing an antenna for a specific Z
is not a good idea in my opinion, as
the amplitude of an element's current is
proportional to the amplitude of its
radiation. Ohms law tells us that at a
consistant power level, the lower the R
(Z), the greater will be the current.

A zero loss transformer would not
reduce the element's current, as the
energy being introduced to the element
would remain unchanged.

Tom Donaly, KA6RUH wrote:
": how do you take the gradient of the current at a point on a
transmission line?"

Not sure I understand the question. Gradient is the rate of change and
that`s the derivative of the current at a given point. Over a certain
path it is the difference between the path ends and can be averaged for
the path.

For convenience, Kraus has collected transmission line formulas. I`m not
a typist so I`ll just say they are near the end of the new edition, page
890. In the 1950 edition they can be fornd on pages 506 and 507, also
near the end of the book.

Work out your own example.

>Which SWR should I trust?
>
>Ken
>
>
>
It's all to do with the knee of the diodes. The rectification efficiency
of diodes drops off rapidly when the level of the applied RF signal is
low.

Assuming that the SWR is fairly good, but not 1:1, with 100W the reverse
detector will get a reasonable level of RF, and will be reasonably
efficient. The forward detector will, of course, get lots of RF, and
will be very efficient. The result of this is that you get a pretty
accurate (if slightly optimistic) indication of the SWR.

At 5W, the reverse detector will get less than a quarter of the voltage
than at 100W, and this will make it fairly inefficient - so inefficient
that the diode hardly works at all. However, even though the forward
detector will also get less than a quarter of the 100W voltage, this
will still be sufficient for it to be reasonably efficient. As a result,
you still get a good reading for the forward power, but essentially
nothing for the reverse. As you are not really seeing the reflected
power, the SWR looks decidedly optimistic.

Ian.

|of a fraud if one did exist.
|
|Or perhaps you simply imagine that all those
|good folks who find my antenna design a
|superior one, are merely deluded idiots, as
|Brian Beasley once accused...

One only look at the deluded victims and followers of the likes of
Jerry Falwell, Jim Bakker, Jim Jones, the Nigerian finance minister,
etc. to realize that hucksters never find a shortage of true
believers.

Let me show you how this works.

I _personally_ guarantee you that my design for a 3-element 20-meter
Yagi will out perform any Raibeam of the same boomlength and at the
same height above ground. (I'll leave out the "electrical
boomlength", whatever that means)

Now it is up to *you* to prove this claim false.

And like any good huckster, as "proof" of the superiority of my
design, I offer these testimonials:

With the antenna at a modest height of 50' above ground and fed with
250' of coax, in the recent ARRL Field Day contest Single-op N7WS was
able to hold a frequency while running < 100 W (SSB) on emergency
power. In only 17 hours of operation 1357 20-meter Q's were logged.
All states and all ARRL sections were contacted.

During the recent YV0D expedition, N7WS worked them not once, but
twice on SSB (this pissed them off, but I'm tired of not being in the
log when I know that I worked them), on the first call, and also
worked them with ease on CW.

>For a mid-UHF fractal antenna, what kind of power can be used to
>transmit, 100 watts, 1000 watts, 10,000 watts...?
>

I've had such antennas at very high QRO, but not for ham use.

Some designs, as with antennas in general, will arc at very high voltages.
Others will not.

It takes experience to pick the design that deals with the specs, including a
HV spec.

That's a commercial issue and beyond the scope of this NG.

|Hi Wes,
|
|Yes I am aware of the difference between the advertising on the site and the
|range results.

So are you going to fix it or not?
|
|As you are aware antennas do not have even gain across the entire band. We
|have designed the antenna to cover the entire 2m band and as a result do see
|a variation in the perfromance across the band, hence max gain.

Huh? So are you saying that you have nearly 3 dB gain variation in 2
MHz.?

|
|And before you cut down my comments, the precision on the results are from
|the softare and we are in the process of redesigning the format to more
|accurately reflect our actual results both modelled and actual.
|Unfortunately our business is antennas and web design.

In a paper I wrote for the ARRL Antenna Compendium, I said,
"Simplified 'antenna analyzers', especially those with digital
readouts can lull the user into unjustified confidence in the accuracy
of his measurements."

Change the words "antenna analyzers" to "computer software" and it
describes this situation to a T.

|
|The results posted on the CSVHF society are valid as the antenna was tested
|with a gain of 11.2dBd at 144.18MHz Horiz Polarization. Design Freq is
|146.0MHz.
|
|We are in the business of designing and selling antennas not developing
|antennas and giving them away for free. However, if your serious about the
|data for the antenna contact me directly so that we can discuss the details
|(email listed below).

My slightly distorted email is above. If you choose to send me your
parameters, I promise to keep it in confidence. I don't not design,
or manufacture antennas (or anything else) for a living.
|
|As to the DATAQ, well I have no answer for that one, as we don't build it or
|sell it. Our software is designed to with run it. Strange though, my
|Toshiba does and so does my SONY through a USB to SERIAL converter.

I know you don't build or sell it, I'm just offering a caution to
those who might be tempted to buy one. It works on my desktop but not
my laptop, which is a pity because I had a portable use in mind.

|
|One final point, the purpose of the posting was that identify that an
|antenna does not always need boom length and elements for gain and that
|there are other ways to achieve this.

Absolutely. One driven element at the focus of a 40' parabola is a
decent antenna at 2-meters.

Regards,

Wes N7WS

"Fractenna" conjectured:
> [Wi-Max] will replace Wi-Fi...

Wi-Max range is slated to be MUCH greater than the normally ultra-short range of Wi-Fi. Wi-Max is to be a 'metropolitan' network with normal ranges in the double-digit miles. That is a critical and extremely 'enabling' difference.

Once established, Wi-Max will enable Internet Radio in cars and Walkmans (etc). Wi-max automobile-PCs in cars (yes, they're coming soon) is a combination that will ~bury~ the old AM/FM broadcast industry. (Imagine what wireless-enabled automobile-PCs will do for drive-by music sharing...)

Also, Wi-Max plus VoIP will shake up the 'smell phone' industry too. Why pay $30 per month to the cell phone bandits when you can have similar capabilities on your bundled Wi-Max account (replacing DSL, landline, cell phone and more) ?

Obviously, in the long run, they'll have to 'cell' the Wi-Max zones into smaller areas for frequency reuse. But to start, the key is the proposed incredible range.

Wi-Max is going to be ~huge~. Much more than the boring old laptops in coffee shops and parks (::yawn::).

Buy your stocks now.

One other possibility, could be mismatched diodes simple test is to reverse
your swr meter (The Antenna to the Transmit connector, the Transmiter to
the Antenna connector, and see if you get the same results. this should at
least test the knee of the "square law response" of low level voltage from
the diodes . for a dual , crossed meter, this jist is to make sure that
the pointers (opposite) are at the same relative positions as measured
in the correct direction, as obviously, the swr curve on the meter will
not be valid-- Do this on both low power, and high power. Tests not
only the diodes, but the coupling links in your swr bridge. Jim NN7K

I've use EZNEC to demonstrate any number of "impossibilities" all
without violating or compromising the modeler's constraints. The
effects were trivial to say the least, but demonstrated that Axioms of
antenna theory had limitations that were unexpressed (until you got to
the graduate level of the same sophomore course work).

>Since
>you can't prove a negative and I know that you know it, I assume that you
>did. If so, perhaps you could post the example on your website.

Well, it has been a great while in this particular instance of path
reciprocity. I did use the scale of range you suggested (and perhaps
further). It was not so much about loss however, but the failure of
reciprocity (a common topic in photography - which, here, is an
aside).

I frequently use two or three antennas in one model, with the
second/third being receive models with termination resistors. They
would be called sniffers in field work or bench work. This work that
I engaged in had no particular demonstration of your curved field
issue (which, through simple abstraction suggests any differences you
would observe would be out several decimal places and beyond the
ability of any instrumentation to resolve with accuracy). Then again,
maybe it did (it may have involved an inclined sniffer which
demonstrated the curvature in one direction, with a corresponding
difference in the other). I would suggest you simply follow this last
speculation and see where it takes you.

I suppose you could search the archives for my name and the key words
of "reciprocity failure" and confine the search to the mid to late
90s.

And don't forget the power line noise will tear this digital trash a new one. Here in Alabama it will be a toss up of which is worse. The BPL or the PL Noise. I bet on the PL noise winning. If not then perhaps my KW beacon on all bands will.

Hi Roy,

For clarity, let it be established that the
term "wire kernel" and "wire model" (the
term used in the NEC2d documentation) will
be considered as one and the same in this
discussion.

That said, I find it extremely hard to believe
that the wire model used for interconnecting tx
lines, which normally would be implemented
only in the special case of unbalanced
terminations, and one that uses the most
resources, would be designated as the
default wire model. It defies all logic.

When asked what criteria your program uses
to determine which wire model to implement,
and why it is not a choice the user can make
- as it should be - you responded with a rather
paranoid and pejorative diatribe attacking my
character... what am I supposed to assume
from that?

In any event, these were honest questions
which you chose to evade, and continue to do
so. All things considered, it is easy to make
the assumption that the thin-wire model is not
implemented in EZNEC, and you're simply
trying to spin your way out of a hole.

Shame on you!

BPL is never getting off the ground to start with. People dont want to be tied to a power line any longer. Look at the dramatic increase of cell phone and lap top computers in so called hot spots.

BPL is dead before it gets going.

This paraphrases the spesific example that I gave

the question would a transformer cancel the increased
> > gain.
Again you paraphased the spoecific sample that I gave
which raised the same question I gave regarding transformer losses
>
> Optimizing an antenna for a specific Z
> is not a good idea in my opinion, as
> the amplitude of an element's current is
> proportional to the amplitude of its
> radiation. Ohms law tells us that at a
> consistant power level, the lower the R
> (Z), the greater will be the current.

Yes there are many laws to remember and I
look at critical coupling as something to remember.

>
> A zero loss transformer would not

> reduce the element's current, as the
> energy being introduced to the element
> would remain unchanged.

Very true but what element would this max energy be applied to?
Via critical coupling the driven element may not be the one carrying
the maximum current and thus screws up conventional thinking.
Energy is one thing but it is current that controls radiation is it not ?.
The particular model I was working on used 50 segments per wavelength
and used element length and diameters determined by my program input .
Thus coupling gains are attained but where it sometimes determined a
element diameter
is so thin it is incapable of carrying the required current.
If I saw a vendor advertise an antenna at 13dbi I would be very suspicious
as it not the norm,
yet very realiseable when using NEC without being tied down to existing
doctrines.
Soooooo ..... I was looking for a datum curve generated by experts from
an all encompasing
NEC program where the final design reflected the real world design without
ambiguities
regarding coupling to coils, elements e.t.c. where lumped loads do not
reflect the real
world appearance.
There have been many responses including one suggestion that a suitable
datum curve could
be formulated from customer claims no less but NONE that responds to my
specific request .
Thus a conundrum still exists regarding programs based on scientific
knoweledge that are held in question
as they do not match real world measurements that spawn most of the
villifying in this group.
Seems like a datum curve could be used as a basis for many discusions where
differences do occur
instead of just arguing for eight years or more and not resolving the
accuracy concerns
Seems like I have come full circle and describing the Presidential debates !

Ian
Would you please describe for me the physical arrangement of an IDEAL
inductance.
I cannot visulise such a thing as I only have seen 'coiled ' inductors
,where each coil has
a scientific and analytical relationship to its adjacent coils which thus
CREATE an
inductance and without which an 'inductance' cannot occur.
I don't want to enter the augument that is ensuing on this thread but just
want to be sure that
there is not an inductance available that is not generated by proximity to
other items including
its own content (wire length)
Using chemical terms, is it an element or a compound if you get my drift ,
since you later
mention that 'inductance.' has a "fundamental physical
property................." that does not change
regardles of a proximity situation.
i.e. Self sufficient.?
TIA

A total current gradient obviously exists on a transmission line
with current minimums and maximums. You can locate those points
with a simple pickup loop. The current gradient is caused
by the superposition of forward and reflected current waves as
described in any transmission line textbook.

"Taking the gradient" seems to me to be unnecessary and just a
logical diversion away from the qualitative conceptual discussion.

Understood but cell phones had some nasty antenna issues in their
early days which for the most part have been overcome.

> I think Wimax has a bright future, but I don't share your opinion that it will
> bury BPL. It seems more likely that it will replace Wi-Fi in extant deployments
> at some point.

Random ruminations:

Wi-Fi is for 300 *foot* radius hot spots. Wi-MAX will be for 2 *mile*
radius hot spots in urban areas and 10 mile radius hot spots in
suburban areas. Strikes me that Wi-MAX is a tad more than just an
updated version of Wi-Fi, yes? As is in no useful comparison
whatsoever.

Wi-MAX aside I'm convinced that BPL will bury itself if not via it's
lousy economics then by the pile of interference issues it'll have to
deal with. Or in any combination thereof. So I'll stick: Whatever
remnants of BPL which might still be around when Wi-MAX gets rolling
will hit the bit bucket of history with a dull thud nobody will hear.

Some *very* heavy hitters are up to their ears in investing in Wi-MAX,
Intel and Nokia are only two of 'em. Who of their caliber is futzing
with BPL? Nobody. Current Technologies? Ambient? . . . gimmeee a
break! I know you can connect those dots Nathan . . .

> how we *know* it's true! If we can't see how it joins up, that means we
> still have work to do. Dividing it into compartments that don't join up
> is lazy and will always lead you false.

Most of our models involve shortcuts. For instance, the shortcut equations
for small loops do NOT work for large loops. Your lumped circuit shortcuts
don't work for distributed networks. When anything in the circuit is an
appreciable percentage of a wavelength, the lumped circuit model doesn't
work. That's why the distributed network model was invented.

> A fundamental physical property like inductance doesn't change its
> behaviour depending on the situation it finds itself in. If you cut the
> antenna wire and insert an ideal, lumped inductance, that inductance
> will behave in exactly the same way as it does in any other circuit.

It won't behave at all in reality because an ideal, lumped inductance exists
only in the human mind, not in reality. If you want to play mind games, be
my guest, but please don't try to pass your mental musings off as reality.

The question is not whether your mental current changes through an ideal,
lumped inductance existing only in your mind. The question is whether the
current changes through a real-world bugcatcher coil that exists in reality.

> If you really looked hard at the math of antennas considered as
> transmission lines, you would find there is no problem whatever about
> inserting an ideal inductance, with no difference in current between its
> two terminals.

An ideal inductance doesn't exist in reality so you are just playing
games in your mind. Every real-world coil has a phase shift, i.e. a
delay. A phase shift is all that is required for the superposed
currents at each end of the coil to be different from each other.

You seem to be saying that the phases of the forward and reflected
currents don't change through a one-foot diameter, one-foot long bugcatcher
coil made from 60 feet of wire? All I can say is, "Get real!"

Art, picture a dimensionless point in your mind. Define that point as
an inductance without dimensions, without capacitance, and without resistance.
There is your "IDEAL inductance" and exists ONLY in the human mind and certain
computer models. Since it is dimensionless, the current into the point and the
current out of the point are the same current because they are the same point
and, of course, the dimensionless point is traversed instantaneously.

Now, without modification, extend that dimensionless concept to a one-foot
diameter, one-foot long bugcatcher coil, wound with 60 feet of real-world wire.
Assert that the bugcatcher coil has virtually identical characteristics to that
previous dimensionless point in your mind. Use a computer model's dimensionless
inductor feature to prove your point.

That's the present "physical arrangement". :-)

Dunno if you heard the debate between Howard Dean and Ralphie boy. Now THAT is what a debate is supposed to be. Dean was pretty civil for the first part, and Nadar actually wasn't boring. But when Dean brought up Ralph's dubious buddies, it turned really exciting!

# 900. WiMAX 802.16a specification

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-20 03:39:36 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <q4mbn0pk1ndtc7tbq4ebipde4ugr265qh6@4ax.com>
Source record: 87995

WiMAX:
The IEEE 802.16 Air Interface Standard is truly a state-of-the-art specification for fixed broadband wireless access systems employing a point-to-multipoint (PMP) architecture.

In order to ensure interoperability between vendors equipment, the WiMAX technical working groups have completed the work for 10 to 66 GHz and has started work for the sub 11 GHz part of the standard.

This requirement eases the effect of multipath, allowing for wide channels, typically greater than 10 MHz in bandwidth.

The standard is designed to accommodate either Time Division Duplexing (TDD) or Frequency Division Duplexing (FDD) deployments, allowing for both full and half-duplex terminals in the FDD case.

The MAC [Media Access Control] was designed specifically for the PMP wireless access environment. It supports higher layer or transport protocols such as ATM, Ethernet or Internet Protocol (IP), and is designed to easily accommodate future protocols that have not yet been developed. The MAC is designed for very high bit rates (up to 268 mbps each way) of the truly broadband physical layer, while delivering ATM compatible Quality of Service (QoS); UGS, rtPS, nrtPS, and Best Effort.

The 802.16 MAC uses a variable length Protocol Data Unit (PDU) along with a number of other concepts that greatly increase the efficiency of the standard.

Practical cell sizes usually have a small radius of around 5 miles or less.

Data rates vary according to modulation rates (1.75MHz to 20MHz) and modulations (QPSK and QAM) to achieve 1Mbs to 75Mbs.

Hi Mike,

That is like watching grannies mud wrestle <yawn>

My best view of a debate was during the '68 election cycle, CBS news, Democratic Convention, ringside color commentators by Bill Buckley and Gore Vidal.

On network TV, coast to coast all day coverage (or maybe it only felt like it), limited channels (the only game on the tube) and if looks could kill, the space between them would have run redder than Cambodia swimming in blood (waiting for Kissinger to spring that genocide).

They parried back and forth in verbal jousts and Gore upped the ante by calling Bill a Crypto-Fascist. Bill sprang across the coffee table between them and tried to throttle him. The moderator was so surprised he watched them struggle on the floor. A quick knee to the groin would have settled it post-haste, but neither had anything to lose.

Today we get candy-asses like Buchasneer and Limabean who couldn't fight a swish with his limp wrists tied behind his back. :-)

Source record: 87998

Grounding a tower does not help prevent it from getting hit by
lightning. It does however help route the charge safely to ground when
hit. A tower may actually be a little less likely to be hit if not
grounded but that is not a good thing to do.

Placing ground rods out in a radius like the spokes of a wheel around
a tower is a good thing. Placing a connecting wire between rods on the
circle is a waste of wire. It would be better to use that additional
wire for additional radials. The current will travel out away from the
tower. Each ground lead going away from the tower will share the
current. There is no significant current difference between the ground
rods so the ring connection does no good.

First a few ground rods should be placed as close to the tower as
possible to have the shortest lead length from the tower. Additional
ground rods placed on the "spokes" going out away from the tower at
distances twice the rod lengths along each spoke.

Having the connecting wires buried going to the other ground rods will
increase the ground system effectiveness also.

Not being struck because you have a good ground system is not proof
that the ground system prevented it.

That's exactly what's done in some "frequency independant"
antennas. You can do it with logarithmic spirals or the
Archimedean kind, take your pick.

There are lots of ways to make inductors, (coils, transmission lines,
meander lines, etc.) but there is only one inductance.

I'll stop right there, Dimensionless objects which relies on proximity
effects
is beyond my ken. To use this as an aproach of dimensional devices with
NEC to prove something is like building on sand This is like using complex
circuitry
and ignoring connection lines that radiate. In mathematics we use a mythical
addition
of root minus one as a sort of gimmic to solve a problem but we always
remove the gimic
before the real world answers are given, yet you want to keep the gimmic,
ala an imaginary
thing which is dimensionless and thus has zero proximity effects even tho
proximitry effects
is what generates inductance in a dimensionless form. And you want me to use
this imaginary
dimensionless aproach with NEC which deals with the real world where
inductance cannot
be dimensionless ? This is where the coil argument started since the field
density inside a coil
is more than that at any point physically and dimensionaly outside the coil
which leads to lumped load errors.
I am hoping that Ian will address the question in a more serious way and not
as a way to
buttress a personal agenda. I suppose I should have made it a seperate
posting so it would
not be perceived in taking sides e.t.c. Actually I modelled the coil to
real world dimensions
with a NEC program with copious segments that supplied current levels at
multiple points
around each turn to get my answers which this thread now suggests that NEC
answers could me incorrect
thus I am following the thread but not partaking in it.
My personal belief is that making EZNEC a part of the debate is a mistake

since it contains
boundaries that most NEC computor do not have and the coil problem is
outside its useable
boundaries or imposed limits.If a lumped load is viewed as dimensionless
then a computor
can be excused as supplying a dimensionless response which can evoke a
'garbage in....'
type comment.
Like most technical things there is nothing wrong with the use of items
such as EZNEC
within the limits prescribed by Roy and the coil question is outside the
useable limits
of the EZNEC program.
This response is not meant to be personal to anybody or any program
mentioned
Art

As usual, zero technical content from you.

Tom, here's a "circuit" for you.

```
+--------------------------------+
| |
source Load
| |
+--------------------------------+
```

The source is delivering 200 watts in the form of V=100V and
I=2A in phase. The load is 4050 ohms. Using your circuit model,
you assert that the current through the source is equal to the
current through the load since it is a series circuit. Yet, if
the current through the 4050 ohm resistor were actually 2.0A,
the power to the load would be about 16,000 watts, thus violating
the conservation of energy principle.

Is there a current drop from the source to the load? Of course!
Does this violate Kirchhoff's laws? Of course not!

Why doesn't your circuit model work? Because the wires
between the source and the load are 1/4WL of 450 ohm ladder-line
thus rendering the circuit model invalid for the application.

YOUR CIRCUIT ANALYSIS MODEL DOES *NOT* WORK ON DISTRIBUTED NETWORK
PROBLEMS!!!

Hi Art,

Read the thread where it is correctly described and stick with a
winner. After all, the difference between the point inductor, and the
helical one offers barely half a dB difference in the outcome. No one
here could possibly measure that spread accurately (about the quarter
of the width of an S-Meter's needle).

>within the limits prescribed by Roy and the coil question is outside the
>useable limits
>of the EZNEC program.

Art,
in EZNEC version 4.08 by using HELIX definition menu in WIRES you can define real coil, with segments. I did that at the beginning of this thread using 10m quarter wave loaded antenna showing the difference in the current at the coil ends and also what happens when you move the coil from 1/2 to 3/4 way up from the feed point. That correlates close to modeling of loading inductance by using stub and what was found by measurements in reality.
If one insists in modeling loading coil as inductance with zero physical size, then you get W8JI results (same current at the ends)
There is a progress, even if some still can't swallow it.

Hello, Walt,

The URLs are OK. Today I could not get to the site either. But I know
from experience that sometimes it helps to shorten the URL. Delete all
after 'technical/' and then go through the menu. I tried it a few
minutes ago and it worked. I downloaded the 1.6 MB Report, and from the

next subtitle I printed the 27 pages Report. Good luck.

yes, its pointed west as the guy at the station has suggested. i did
go up and rotate it through the compass points just to be sure there
wasn't a better direction for it.

> As you are using two antennas, how are you connecting them to the same
> TV or VCR? As you have tried this antenna individually and still
> found no happy conclusion, it would seem to be an elemental problem.

in seattle, this antenna scheme is sold specifically to pull in a
station that is west of the city, when all the other local stations
are in town. so my main antenna points north toward downtown seattle,
and this smaller one, that i mounted as instructed (on the same pole)
points west. there is this small plastic box that is part of this
kit. it too is mounted to the pole. i guess it's a splitter. i plug
the little and big antennas into the box and a third cable runs down
to the house. the station is not terribly far away - it used to come
in fine, and they haven't degraded the signal. i live kind of on a
hill so i don't think a building or hill is interfering with my signal
path. when the coax connector is plugged into the tv, and all the
other stations come in, channel 13 is snowy. you can barely make out
what is going on.

The difference in the outcome of the currents is way more
than half a dB. It's more like 12 dB.

Got news for you, Richard. The current drop from a current
loop to a current node is NOT a violation of Kirchhoff's laws.
It is a characteristic of distributed networks.

> instead the 300 ohm (if any) connectors?

i believe i am touching both pieces, ever so slightly. i tried one of
the other cables in the scheme that has a longer inner conductor - to
allow the connection of that alone, but it didn't improve the picture.
perhaps i really am only touching the gound part of the coax to the
ground part of the tv connector. that would explain why when i fully
engage the connector, the signal gets crappy. i will try some other
combinations to see if i can clarify what i am doing.

>

i mounted and pointed west a smaller antenna, onto the same pole as my
main antenna. there is a box on the pole as well where the two
antennas are connected and a third cable runs to the house.

> In any case, your problem is probably 'up the pole.' If it worked before, i
> t should work now; unless conditions have changed. Have any tall buildings
> been constructed between you and the transmitter?

no new tall buildings. my hunch is that the connector for the smaller
antenna, or the part of the splitter/combination box up there that is
for the smaller antenna, is failing. all the other stations still
work beautifully.

> My best advice would be to have the same people who installed the array (or
> other competant service people) service it. It sounds like your technical
> knowledge is limited, and I doubt you're going to want to climb that pole...

my technical knowledge is for sure limited, but i installed all this
stuff once and it worked. i guess i will be up on the roof this
weekend, taking a closer look at the small antenna connections.
thanks for the advice:)

Hi OM,

By this I presume you live south of Kent in Auburn or Puyallup (I live
in Seattle too).

TV in this area is so ubiquitous that you should get channel 13 by
waving your....

It sounds like you are trying to put Channel 13 into the UHF connector
instead of the VHF connector of your TV. The box you speak of sounds
like a VHF/UHF combiner, and I don't hear its twin at the other end of
the line being used (a VHF/UHF separator). If you are not using or do
not watch UHF (don't watch Channel 22?) then you need a simple
combiner. However, I think that is distinctly unlikely that you would
not be watching FOX - or maybe it's WB, I've gotten so use to the
cable channel mix I've lost track of the over-the-air slots.

Anyway, this sounds like an UHF/VHF splitting/combining problem now.

The current in a series loop is NOT constant when the loop is a
reasonable percentage of a wavelength and there are reflections
present. Please provide proof that violates Kirchhoff's laws.

I am contemplating on combining the signals from two antennas onto one cable using some sort of an "RF combiner" (is this the right term? Is "RF mixer" a better term?).

The idea is that I combine the signal from a dedicated omnidirectional FM antenna and a dedicated omnidirectional VFH/UFH antenna, since I have only one cable run in the house and I want to use it for both FM and TV reception.

Does this idea make sense at all?

If so, what's the market name of this "RF combiner" device I should be shopping for? Can you recommend a specific one? (does Radio-Shack have such?)

Thanks,
Daniel

Fractal antennas ... turned out to be useless. That's how I understand it.
It is not a myth, as someone here said it. Drawing "fractal dipole" is shown
in "Antennas for all applications" - there is such a book. It,
anecdotically, does not do you much of anything.
Looks fancy, that's it.

There were bunch of articles promising miracles, but it did not work
according to the promises, otherwise we would hear about it, see them
around.

It sounds like you no longer have a good circuit up to your antenna, and by
just touching one conductor to the TV antenna connector your downlead is
acting like a "longwire antenna", which gives some signal. When it is fully
connected, the shield is grounded and now little if any signal reaches the
TV.

Hi Jack

That is probably true and the reason the project was abandoned!

Step Leaders can form and reach up from almost any grounded source, but more often than not, the eventual discharge causes no appreciable harm.

The small study I helped with was some 25 or 30 years ago and I really don't remember too much of the details about it, other than apparent physical damage was almost always within our red zones.

I don't think the spheres we were using were anywhere near 300 feet in diameter, if I recall they were like 36 feet, 72 feet and 108 feet. Regardless of the size of the ball, on most structures the red zone was in the same place. Only on very tall structures would the red zones be more than one zone at varying heights along the structure.

I do remember our accuracy for the town we modeled was very high over 90%, but then too, we had a LOT of red zones as well since we were using like 5 different sizes of balls to mark these zones.

You also have to remember, back when I was in Skewl, the correct answer to a question was considered WRONG. And the wrong answer correct. EG: Number of Elements, the WRONG answer the skewl demanded as correct was 45 Elements NO MORE NO LESS, and you had better not forget the NO MORE NO LESS phrase!
There are 92 Natural Elements and about 114 Elements Maybe More.
But if you put that on your exam, you were graded as the answer being WRONG.

MOST of the stuff I learned in skewl was Erroneous in Real Life, I don't doubt that our lightning experiments were also!

Hi Richard

If you recall, I lost a tower to a lightning strike.
Took us forever to figure out why it came down, but we finally did.
Water built up in the leg of the tower, the lighting turned the water
to steam causing the leg to explode.

In some minor cases we found the places where lightning struck through
burn and/or pit marks combined with visual observations of bystanders!
Other times, the foot long melted out section of guttering was a dead
giveaway along with the distortion of the rest of the guttering to
ground.

This Richard agrees a refresher course could help. I no longer read the Proceedings of the IRE for fun. It`s been over 50 years since I last darkened the halls of academia.

I remember a few things. One hangup I see here is the rule that the current in a series circuit is always the same everywhere.

True for circuits small in terms of wavelength. False for unmatched (not terminated in Zo) circuits of a size significant in terms of wavelength.

The standing-wave antennas of this thread are less than 1/4 wavelength, but they`re still significant in terms of wavelength with or without loading coils. They are open-circuited and make a big reflection from their open-circuited ends. This reflection causes a current which varies from zero at the open-circuit end to something substantial back a ways from the open-circuit. Between substantial and zero is a current drop.

My favorite author. F.E. Terman depicts this current distribution in a dipole (two 1/4-wave antennas back to back) in Fig. 23-2 on page 866 of his 1955 edition. For a whip worked against ground, the current distribution is either half of the dipole representation.

Look at Fig.23-2. Anyone can see the current drops to zero at the antenna tips. Loading coils won`t change that. Coils added to bring total antenna inductance to resonance with its capacitance occupy space. Current through a loading coil takes time to traverse the coil. By the time current has made the trip through the coil, current arriving from the source is out of phase to some extent with that arriving through the coil. The delays in transit to both ends of the coil are likely not equal. The inequality in phase results in a difference in volts, amps, and impedance at the two coil ends.

Recall, we are discussing r-f, traveling as a wave from both terminals of a generator. It is not d-c emerging from one battery terminal and entering another.

Cecil is exactly correct in his characterization of how waves supeerpose to produce standing-wave variations in voltage, current, and impedance in the total series circuit.

Proof has been offered by modeling, and measurement. You may accept or reject the observations of others. You could also make your own.

Best regards, Richard Harrison, KB5WZI

Yuri
I was relying on statements from Roy in the past where close spaced wires
causes errors.
In a inductance coil each wire is in close proximetry to other wires in the
coil that undergo
voltage changes Thus by his statements his limited number of segments
available could cause errors.
It was for this reason my modelling picture was the image of a real coil
with close spaced
coils und unlimited segments available which when increased did not change
the supplied.results,
the test for finality in modeling.
One of the reasons I chose this aproach was when modeling critically coupled
coils, lumped loads
which are imaginary and dimensionless gave problems with critically coupled
distances from the
center line of a coil ie inside the coil, to distances to outside the coil
in a single plane, as well as the
capacitive coupling provided by the length and shape of the coil
To me it was important for the program to do it's job with a real life
coil without any intrusions
and assumptions imposed by the operator. If a program has limitations
imposed then it is a sign
that human overuling intervention is required to prevent the program from
running amuck.
But as I stated earlier, I have no intention of getting involved in this
thread with its infighting
when I respect some people from both camps.and where as previously stated by
a poster
some responses are posed like a language but are non decipherable

An antenna loading coil may have unequal current ingress and egress without violating Kirchoff`s law the same way a speaker matching transformer or pi-network does. The input and output impedances are different, though the power input and output are nearly the same.

Hi Gary, I understand completely. Lightning attaching to an object is not where the damage comes from, it's the way the damn stuff *leaves* that causes the problems! ;-)

Notwithstanding your hopefully unique experience where water in a tower leg was superheated. Some private company specifications call for an air terminal and grounding electrode conductors on all their towers, including at each fixture (antenna) attachment point.. Even most tower manufacturers call this unnecessary, recommending bonding of air terminals (if used) to the tower legs only. But I suppose that a grounding electrode conductor from tower-top to ground *could* have prevented your loss, by reducing some of the current in the tower legs in favor of the heavy GEC coming down alongside them.

Best regards,

Jack

> Best regards, Richard Harrison, KB5WZI

==========

It is important to make clear it is NOT a linear taper.

The current and voltage are distributed along the helix in Sine or
Cosine-form as with a 1/4-wave resonant wire antenna.

Adding conductors to its ends merely truncates the same kind of
distribution.

This applies to both short-and-fat and long-and-thin helices.

Instead of confusing the issue by stretching the imagination and messing
about with reflections and standing waves, analysis of behaviour is more
simply and accurately done by basic transmission line formulae.

Which automatically takes the coil's all-important capacitance to the rest
of the world into account.

Zo = Sqrt(L/C).
Velocity = 1/Sqrt(L*C).
Phase shift = Omega*Sqrt(L*C).

It's as simple as that!

PS. Replace "does not usually eliminate" with "never eliminates"

Since most set nowadays have the U/V splitter built in, I doubt that is what he has. Up the pole is probably a simply 2 to 1 wideband splitter. I'm assuming his 'main' antenna is an 'all channel' type, and the secondary is cut specifically to channel 13.

I'd go out and buy a new splitter, some coax, connectors (with rubber boots and weatherproofing grease). Somewhere there's a dodgy connection; and if he has all those on hand, he'll be able to fix it. Perhaps he can reuse the old coax, if he doesn't have to cut off too much in order to 'make' the new connections. If water has migrated down the coax, he's better off to replace it anyhow.

I'd also pay particular attention to the connections on the antennas themselves, as well as verify their general condition.

I'd bet anything he'll find some corrosion up there somewhere....

With a system set up as described, I'm surprised he doesn't get some ghosting on channel 13 from the reflected signal coming off his main antenna. If so, trapping that channel before the splitter (combiner) would reduce the effect.

The standing wave current profile along, for example, a quarter wave radiator is a cosine function. The gradient then would be the derivative of the cosine function which is a -sine function.

I have been given a 50 ft Rohn tower (galvanized).

Problem is, I have to get it down. and I have a couple questions.

Weight of each section?

estimate of a resonable charge to have someone do it for me? I don't like climbing

Is it worth paying 160 bucks to rent a 50 ft cherry picker to do it?

Thanks

Jonathan

The URLs are OK. Today I could not get to the site, either. From
experience I know that if you shorten the URL, it sometimes helps.
Delete all after 'technical/', and then go through the menu which will
appear on the screen. I did so and it was OK. Good luck.

Yep, the feedpoint is at a current loop (max). The open end of the quarter wave radiator is obviously at a current node (min). There are electrically 90 degrees of signal between the current loop and the current node on a standing-wave antenna or on a transmission line with standing waves.

> Actually, no rational response is even possible.

Hi Roy,

If what I am saying makes no sense,
then the information contained in the
NEC2 documentation must be a fairy
tale and you must be Merlin the
magician.

I invite everyone to take the time to
look at section 3 "Transmission line
modeling" on page 72, of the NEC2
documentation.

http://www.nec2.org/other/nec2prt1.pdf

It explains the uses of both implicit and
explicit tx line models, and under what
conditions the explicit model (thin-wire
kernel) should be used.

Looking a look at previous statements;

First, the thin wire kernel is invoked
automatically:

> The extended thin wire kernel is invoked automatically when the model is
> such that it's needed, according to the criteria given in the NEC
> manual.

Then the 2-port network is invoked
automatically:

> I clearly stated in an earlier posting that EZNEC implements the
> extended thick-wire kernel as required by the model. (The thin-wire
> kernel is the default.)

And the thin-wire kernel now becomes
the default. ("default" implies no need
to "invoke" as it is the preferred function
by default - which makes no sense,
since the 2-port network has the most

common usage - W8JK, log periodic
dipoles, etc., etc., and uses less
resources.)

The NEC2 documentation even
suggests there may be instances where
both models should be implemented
simultaneously.

When asked for an explanation of these
contradiction, I get my character
assassinated instead.

So now we're supposed to believe either
the thin-wire kernel or the 2-port network
is invoked automatically, determined by
a *mysterious* set of criteria.

Mysterious simply because that criteria
cannot be divulged...

This is real science, indeed. Given that
no one can ascertain which tx line model
is being implemented, it leaves any
resulting outcome ITR in question!

I suggest we have here a situation akin
to VP Cheney giving disingenuous excuses
as to why no one should see the records
of his covert energy meetings.

Stonewalling will prove to be an exercise
in futility as the truth will come out, one
way or another!

Source record: 87953

Hi Daniel

Generally a mixer in radio terms is a device where two frequencies are input and the sum or difference of them is the output. So you are talking about a combiner..

I think you'll have some trouble with your intentions.

It is relatively easy to combine the signals from two antennas and then split them into two receiving devices. (The antenna combiner might be the same as the splitter only connected the opposite way. Its usually a passive device so will work equally well in both directions)

The problem is that since the bands of use are similar you cant stop (say) the FM omni receiving some signal from the TV band transmission appearing at the input to the TV. This will most likely cause ghosting or other degradation.

I suspect that you mean unidirectional VHF/UHF antenna rather than an omni. Using an omni is very likely to also create TV ghosting.

You could conceivably notch the output of the omni to not pass TV signals but by now the project is getting kind of expensive.

I suggest you just use the one TV unidirectional antenna and have a single splitter inside the house connected to the FM radio and TV. You may get sufficient FM signal for your needs.

You are looking to buy a TV splitter to run two TV's in the house. Shd be pretty cheap.

Cheers Bob VK2YQA

Hi Jonathon, a lengthy discussion ensued on this group months ago, regarding the failure of a home-made gin pole and near disaster avoided by some very capable Parisians. Theirry's LUXORION website has outstanding information about all aspects of the hobby, including tower erection. But he adapted this post of mine regarding the mindset of amateurs to be jack-of-all tradesman (even I don't claim that ;-) The full topic and article can be found at:

http://www.astrosurf.com/lombry/qsl-tower-assembly6.htm

It reads in part (Thanks, Thierry, for your outstanding work):

Jack
--

Take care assembling an antenna system

If you are not confident and used to erect antenna towers, do not entrust the job to close friends or so-called skilled radio amateurs... Your life and the one of your friends is more important that sparing a few money in doing the job yourself without competences.

Here is the comments of Jack, an ironworker in this regard : "there are some places and some jobs where if you make a mistake, people, either yourself or others or both, will be killed. Amateur Radio is not defined as one of these occupations, and no amateur has any business working aloft with rigging and equipment unless he was properly trained in that field. That certainly doesn't stop many from doing it, but it doesn't make it safer because they

survive it. The skills sets that seem to congregate in radio are amazing for sure, and the field-expediant thinking and can-do attitudes are good for all involved in the hobby.

But there are some things better left to professionals. Anyone who doesn't think a lot of Ironworkers die doing what they do better than anyone else could, is just delusional. The bravado I've witnessed from so called antenna-tower experts far outweighs their knowledge of safety, strength of materials, rigging principles, or safe working aloft. Even the better ones at it are not properly qualified to train others, and so often enlist any brave soul they can find as riggers, connectors, ground support, etc

When a low quality gin pole breaks...[ picture ]

Radio amateurs are not riggers! You are old men who have no business up in the air. You belong ON THE AIR, not in it ;-) Paste those pictures of your rigging days upon the club walls and stop your friends from believing they can think these jobs out. They can't erect an antenna tower in certifying at 100% that they will never incur the least risk. One or another day you will have to discover a new principle, strength/weakeness, fault, improper manufacturing or material failure, improper tools, breakage of tools, physical exhaustion of a team member at a critical time, unexpected wind condition, improper response to a command or order at a winch, line, etc. And each time those things happen, your fingers, hands, feet and possibly life will be at risk. It comes with the understanding that all injuries happen between 0-10 meters (0-40 ft). After that, you're either dead, or wish death would release you from the disfiguring and crippling pain.You better get used to the fact that you can and will have injuries so bad from a 2-10 meter fall into or around steel that you will never be the same again, if you live.

All the blind leading the blind. I happen to know better than to work with untrained people at the effort of erecting antenna towers. I knew better when I erected steel as a professional and I still know better 20 years later. But some people's purpose in life is to serve as a warning to others. Don't let one of your friend's falling to his death make your club that purpose. Hire a professional company and take pictures from a safe distance."

Jack, Journeyman Ironworker.

Regularly ham magazines highlight similar accidents, sometimes involving a crane and a truck... So think twice to the risk you incur is doing such a job alone or with friends but without know-how.

## 957. Re: Tower Help 50 ft Rohn

depends on the type, anywhere from #25 to #75 for common ham sizes.

>
> estimate of a resonable charge to have someone do it for me? I don't
> like climbing
>

depends on condition, how much room there is to work and what is on it for
antennas if anything. i could drop it for $20 if you didn't care about the
condition, or you could pay a pro $1000 to remove it from a tight yard with
antennas on top.

> Is it worth paying 160 bucks to rent a 50 ft cherry picker to do it?
>

yes, if it comes with a qualified operator who knows how to handle a tower.
no, if its a drive it yourself and learn on the job rig.

my best suggestion is to ask hams locally who really knows how to do it
right and who has the right equipment.

>
> Now it is up to *you* to prove this claim false.

Since you are making the claim, and
there exist untold numbers of Raibeam
antennas that have consistently beat
antennas of your design (a yagi is a yagi)

in pileups, etc., the onus would be on
you to prove your claim is valid.

Conversely, if there were thousands of
your 3-element 20-meter Yagis that have
beat out the Raibeam antennas in pileups,
and the Raibeam guy makes such a claim,
then it would be up to the Raibeam guy to
prove his claim was valid.

It is all a matter of what has been
established by many instances over
time.

>
> Etc., etc....
>

It is a well know fact that Pat Murdoch,
ZL1AXB and I, both running 4 element
Raibeams @ 40 ft, held a daily sked
for close to four years, throughout the
bottom of the previous cycle on 10 meter
SSB, with power levels never exceeding
500 watts PEP. In only about 5% of the
total contacts were the sigs too weak to
hold the sked.

... the only signals on the band... :)

With that antenna, Pat won first place,
single op CW, in the ARRL 10 meter
contest both in 1996 and again in 1997 -

the only years he participated.

http://www.raibeam.com/page11.html

In the years he participated in the WPX
and CQWW contests, you will find Pat
listed in the top 10m positions as well.

Now, addressing your first assertion:
Pat can hardly be a deluded Raibeam
*cult* follower, since many of his
experiences are a matter of record.

And that does establish something.

>I was relying on statements from Roy in the past where close spaced wires
>causes errors.

Roy outlined the limitations as far turns spacing for minimum error, but for the purpose of illustration, the HELIX menu is a big help in modeling or studying the effect of loading coils. In my original example I tried to obey the limitations and wanted to demonstrate that EZNEC can model real life coils and display the current distribution across them.

This is especially important when modeling parasitic beams with loaded elements.

You still don't get it, Cecil, which is o.k. since I didn't expect you to. I don't doubt that Yuri can find a coil that exhibits a different current at one end than at the other; I have an antenna that exhibits the same behavior, and I made it that way on purpose. However, the term "current drop" as used by Yuri was wrong. There is no place for it in electromagnetic theory, and if you had known enough theory to understand that, you wouldn't have answered as you did.

I don't hook equivalent circuits up to my antennas, Cecil, and I'm surprised that you do. Most of the transmission lines I've ever dealt with had one inductance which the theorists wouldn't think was as important as the inductance per unit length. Besides, you missed the point again.

Hi Richard,
you've hit the nail squarely on the head. The validity of
the whole argument boils down to whether or not you can safely neglect
the effects of the physical dimensions of the inductor on the behavior
of the antenna. It looks to me as if you can, but some of the other
fellows on this newsgroup seem to be as much interested in
characterizing Tom Rauch as a rat as they are in verifying some
antenna effects due to the properties of real loading coils.

Source record: 87959

A good way to check the validity of an EZNEC helix model is to create the helix by itself, run a wire from one end of the helix to the other right through the middle of the helix, and put a source in the middle of the wire. Specify a low enough frequency that the helix will be small in terms of wavelength. I've found the source reactance to compare quite favorably with the reactance of the inductance calculated by Reg's program for the same physical dimensions. The self resonant frequency comes out quite close, also. The Q should be in the same ballpark, provided wire loss is included in the model, although radiation will lower it some in the EZNEC model. (The source resistance with wire loss set to zero is the radiation resistance. As long as it's much lower than the resistance with wire loss included, the effect of radiation will be small. If it's not much lower, reduce the frequency.) As I mentioned before, EZNEC doesn't model proximity effect (significant only when the turns are pretty closely spaced) but I don't think Reg's program includes proximity effect, either.

Hi Richard,
current is the same everywhere in a series circuit only
when you can neglect the length of the components. Network theory is
supposed to be an abstraction that is close to being accurate only
at low frequencies and short dimensions. So, I agree with you. I
don't agree with the term "current drop" because, even in a transmission
line, current, or more properly, current density, doesn't act like a
potential of any sort to which you could ascribe a "drop."
You probably think this is nitpicking. I don't think it is, any more
than Yuri having a fit over how much the shape of the current is
changed in a short, inefficient antenna by a slight change in where
the current bends, ie whether it's at the beginning or end of the
loading coil.

Hi Art,

FS = free space :)

Modeling in FS, using dBd as a reference
eliminates ambiguity.

All grounds are not equal. Including ground
effects in antenna type models that are not
ground dependant, does not reflect the
'real' world, IMO.

Critical coupling is simply a means to
attain element currents of a higher
amplitude than what can be expected
when one element is excited parasitically.

> >
> > A zero loss transformer would not
> > reduce the element's current, as the

Max Energy?

I was referring to the element the transformer is
attached to.

> Via critical coupling the driven element may not be the one
carrying
> the maximum current and thus screws up conventional thinking.

Ummmm...

Critical coupling is a state where currents
of equal amplitude flow in two inductors that
are in close proximity, as a direct result of
the coupling. Critical coupling results in a
common field as well. This also applies to
wires (elements).

> Energy is one thing but it is current that controls radiation
is it not ?.

Yes, and that's what I had said previously.

> The particular model I was working on used 50 segments per
wavelength
> and used element length and diameters determined by my program
input .
> Thus coupling gains are attained but where it sometimes
determined a
> element diameter

I suspect there can be many examples
where this occurs, but not necessarily all
are the fault of software. However, we
both know from experience, software can
be problematic in this regard.

> Seems like a datum curve could be used as a basis for many
discusions where

... but when one fails to include certain
salient functions in their software - software
that is the basis for such arguments, there
is no way the arguments can be resolved
simply because there is no guarantee that
the software will be consistent with
empirical data in all cases, despite a high
order of hubris to the contrary.

Jim,
current, in a wire, is the total current density integrated across
a cross section of the wire. It's a vector, as is the current density.
Now tell me, how do you take the gradient of a vector? David K. Cheng,
in his book Field and Wave Electromagnetics, defines the gradient
operation this way: "We define the vector that represents both the
magnitude and the direction of the maximum space rate of increase
of a scalar as the gradient of that scalar." He wrote "scalar,"
not "vector," Jim. You and the rest of the boys are acting as if
current had magnitude but no direction, whereas it has both.

The catalog lists the 25G (most common type for hams) at 26 pounds per section. Look here for some info on the towers and what Rohn recommends as to putting one up.

http://www.rohnnet.com/ROHNNET/rohnnet2004/html2004/index.html

Think I payed about $ 40 per section for some good looking ones that were on the ground. Make sure there is a way to jack the sections apart and the bolts may be rusted , especially if the Rohn bolts were not used.

Not sure why you don't like gradients, Tom. I'm sure Mr. Cheng is
undoubtedly correct, but I'm just as sure he didn't intend that sentence
as any sort of definition of the term "gradient". That's something you
have apparently read into it. The gradient in our case (since you
proposed the question) would be expressed as the superposition of
forward and reverse currents, with magnitude and phase (or direction if
you prefer) written as a function of either position or angle *along*
the radiator. It's nothing fancy. Honest. It's simply the rate of
change of current as a function of position. The gradient across the

radiator at any given point along the radiator could then be determined using some additional parameters - if someone were really that interested in it (which I'm not).

Uhhh, I hate to break it to you, but the antenna handbook has *both*
descriptions within it's covers. One says the current taper is fairly
constant, and one says it can vary.
>
> Just watch W8JI to massage his web page and twist out of this one (yet another
> egg in the face :-)

Who cares what he does or thinks....
You take this stuff too personal I think. Also, you have a tendency to
be overally smartass with some of your descriptions of people, or the
way they think, or the theories they support. Or the names you make up
to call them. IE: You once called *me* Virginia... You can inspect me,
and if you find a female apparatus "taco shaped", or big tits, I'll
give you $1000. You would get much more respect as far as this coil
current taper theory, if you weren't such a frigging smartass about
it. Just state the facts, or what you observe, and leave the horsecrap
and childish names out. Just my opinion. MK

Source record: 87969

try a tube of flitz metal polish and you dont need that much
just squeeze some from the tube to your hand about the size of a pl-259

then just rub it all over the aluminum with the palm of your hand and use
a light force but a strong enough one to make some friction ,
and you will notice the aluminum turns black.
this is good
then while the polish (black ) is still moist wipe off with a soft cloth
like a old bath toel and the more you rub the brighter it becomes and keep
rubbing till all oxidization is off of the antenna .
and then wait like 15 mins and buff it up again and youd be suprised at
how much more oxidization the buffing towel /rag is still taking off and
buff to your desired shine.
ps. you can also use easy off on you aluminum to remove heavy oxidization
but be quick to wipe wash it off, because it will eat your elements ... but
if your quick it works great...
I also shine boots, brass artillery shells and if it aint shiny It aint
worth keeping....
FLITZ can be bought in 5 lb cans.. and its great...

Gary Deutschmann wrote:
"If you recall, I lost a tower to a lightning strike."

Yes. I was saddened by Gary`s misfortune.. My recollection of the event is that the tower was aluminum. It seems there may have been a poor electrical connection between tower sections which generated first great heat. There was a lightning induced failure of one of the tower legs, if I remember.

The commercial towers erected by one of the companies I worked for, all had a copper cable about like a welding or jumper cable riunning the length of the tower, connecting the top plate to the ground system for the tower. Deep ground rods were connected to each tower leg.

I encountered these towers upon joining the company. I would not have so specified those tower-length cables in those big steel towers, but it must have worked as we never had any lightning damage to the towers. In Gary`s case, such a cable might have prevented a melt-down.

Best regards, Richard Harrison, KB5WZI

>
> I'm not sure if I follow this correctly...
> please elaborate further.
>

Certainly
To attain maximum gain per unit length the model dimensions
were all variables as was the number of elements. Not only
was the driven element current often less than another element in the array
it was sometimes found that the maximum current element required a diameter
of a few thousanths that was not sufficient to carry 1Kw.!
Obviously the gain attained was over ruled by the inability of the element
to meet operational requirements.
I might add that I use fibre fishing rods for my antennas where I can apply
the correct
wire diameters ( or aluminum foil) to an array without being encumbered by
mechanical restrictions.
This removes me from the normal restrictions applied to antennas where
element diameter
is pre-controlled for mechanical reasons which often conflict with
scientific requirements
The above statement does conflicts with your assesment stated above
regarding critical coupling
but this is what I found and I will leave it at that
Regards
Art.

Hi Richard,

There is no such Kirchoff law of two separate points of current, that is Kirchoff's voltage law. A point (singular, the only component of Kirchhoff's current law) has no dimension, any departure from this necessarily excludes itself from strict Kirchhoffian analysis.

M2 does currently make a 14 element 222 MHz antenna, however you can contact them to see if they have the manual still on file.

This is the statement that M2 posts, regarding support for KLM antenna products:

We here at M2 have decided to support the users from the now defunct KLM as best we can.
Basic Technical Questions regarding M2 products can be sent to one of the following:
Wyatt - M2 Tech Support
Matt - M2 Tech Support

If you have multiple questions regarding complete systems, including: H frames, masts, and tower information, please contact us by phone, this will save all of us valuable time.

Hours of Operation: 7:30am - 4pm PST M-F
By phone: 559.432.8873
By fax: 559.432.3059
By mail:

==========

Yes it does!

But you can forget it. It doesn't matter except when calculating efficiency.
It has no affect on how the thing works which is what you are all
so-aggressively fighting about. You'll soon be using assault weapons.

Program "Loadcoil" also includes the ALL-IMPORTANT COIL CAPACITANCE (which I
suspect Eznec does not - I never use it) - the existence of which the
whole set of you block-heads, so-called electrical engineers, appear to be
entirely ignorant.

We ARE dealing with alternating currents.

Oh Boy - I enjoyed typing that! ;o)

To All who endured the string of non-answers, Greetings!

I cannot say that I could add anything substantial towards resolving your issues, however, the tenor of your questions leads me to believe you would appreciate some fundamentals on the topic. Visit: http://www.qsl.net/kb7qhc/antenna/fractal/index.htm

I would warn you, if you do not have a high speed connection, some pages may take a while to download (also considering a slow server at times). The various links that you will find at this page constitute the single greatest exposure of the topic on the web (the commercial outfits are pedestrians along the freeway of information). There are more than 300 pages. illustrations (supported by pages of their higher resolution graphics) and technical details.

Be forewarned there is nothing about construction details. Their mere appearance should yield the reason why.

M2 does currently make a 14 element 222 MHz antenna, however you can contact them to see if they have the manual still on file.

This is the statement that M2 posts, regarding support for KLM antenna products:

We here at M2 have decided to support the users from the now defunct KLM as best we can.
Basic Technical Questions regarding M2 products can be sent to one of the following:
Wyatt - M2 Tech Support
Matt - M2 Tech Support

If you have multiple questions regarding complete systems, including: H frames, masts, and tower information, please contact us by phone, this will save all of us valuable time.

Hours of Operation: 7:30am - 4pm PST M-F
By phone: 559.432.8873
By fax: 559.432.3059
By mail:

I'm not exactly sure of the type 25 45 etc. Originally it was a 60 ft dispatch tower for a towing service. They moved it once and it became a 50 ft. both applications the tower was bracketet to a building about 25 ft up. Is there a way to determine the tower type?

I thougt it would be relatively easy to do this from a bucket.. Come along side, unbolt it. then go above and lower it with a rope?

Thanks for the correction regarding proximity effect. In that case,
Reg's program should report the loss more accurately than EZNEC when the
turns are very closely spaced.

Yes, indeed, EZNEC does account for the capacitance -- it comes about
from the coupling of fields between turns, which is at the heart of the
fundamental NEC-2 electromagnetic field calculations. As I said, the
self-resonant frequency reported by EZNEC is pretty close to that
calculated by your program.

Hi Wes,

Unsubstantiated in your mind perhaps...
but there are many with first hand
experience ITR who would strongly
disagree with that baseless opinion.
Baseless, in that it lacks first-hand
experience to give it substance.

BTW, That was a money-back
guarantee, and in 8 years, the only
refund requested and issued, was
because the poor guy's wife had a
cow over the idea of a beam above
the house. Apparently he failed to
inform her of his plans...

Perhaps you should argue this with
Dr. Ken Asmus, VA3KA , a scientist who
conducted a shoot-out in Canada...

"The Raibeam RB-36x was installed late fall last year (October '00). For the next few weeks I used the Raibeam heavily and was extremely pleased with it's performance. In nearly every comparison with my A4 it was equal or stronger in signal strength. In many QSO's, both long medium and short range, and on all 3 bands, the RB-36x was 1-2 S units

stronger. This was both surprising and pleasing considering the RB-36x is about 15 feet lower than the A4. Using the Raibeam I was able to work ALL the major DXpeditions in the last year (on 20-15-10 meters SSB/CW and RTTY) and was the top Canadian in the 2001 ARRL DX contest (SSB) 10M single band with 1400 QSO's."

You can see a photograph of the two
towers and beams at:

http://www.raibeam.com/page23.html

The RB-36x has 2 elements for each band,
interlaced on a 14 foot boom, and weighs
only 36 pounds.

It seems inconsistent that you repeatedly
cry "unsubstantiated" then refuse to
consider substance. Though I suppose
if you bothered to check out the contest
records, it may raise havoc with your
unsubstantiated opinions, perhaps?... hi

I think you're talking about a splitter - about $2
give it a try
by the way - that 300-ohm flat cable has lower loss than the coax so if you
have a long run from the antennas, keep that in mind

Actually, he did. It's the accepted definition of the term in
electromagnetics. You and Cecil are using the term in a more
general fashion which you've made up for the purpose. It doesn't
make much sense in an elecromagnetic setting. Similarly, Yuri,
Richard and Cecil made up a very loose term "current drop" for
a change in current at two ends of a coil. That was misleading
and wrong if they were trying to convey something about the
electromagnetics of a coil, which they were. I've seen you fellows
pick each other to death over trivia time and again. It's time
you paid attention to what you write.

That's something you

I've been in Las Vegas for ten days and didn't see Yuri's posting.
All I know is there is a "current drop" from the current maximum
point to the current minimum point on a transmission line with
reflections. So exactly how did Yuri use "current drop"? If it is
through a mobile loading coil, I explain exactly how that happens
on my web page through the superposition of the forward and reflected
currents. For the typical base-loaded or center-loaded shortened
mobile antenna, If+Ir at one end of the coil is NOT equal to If+Ir
at the other end of the coil even if the two currents through the
coil are of constant magnitudes. I have explained that multiple times
here with no disagreement.

For typical standing-wave antennas with loading coils:
The forward current through a loading coil is reasonably constant.
The reflected current through a loading coil is reasonably constant.

The two above facts are obeying Kirchhoff's laws.

The total current is the sum of the forward current and the reflected
current and results in a cosine function standing wave on the antenna.
The differing phases of forward current and reflected current is what
causes the variation in the total current, i.e. the current drop.

The current drop in a standing wave antenna is similar to the current
drop in a section of transmission line with reflections. The governing
equations can be found in any EM textbook and for lossless situations
are of the form:

Itot = If*e^-yz - Ir*e^+yz

Losses to radiation or I^2*R add another couple of e^-2ad (attenuation)
terms.

You guys have completely missed the point. The argument is not about
the behavior of the antenna. The original argument is/was about the
current in a real-world antenna loading coil. The behavior of the
antenna is irrelevant to that original argument.

Webster defines "drop" as "to become less". Seems to me, the current
"becomes less" as one moves the measurement point from a current loop
to a current node on a standing-wave antenna.

Hi jak,

Reflected signals on a nearby antenna (like one on the same mast) is
going to be totally invisible. The scan line crosses the screen in
62ï¿½S and an RF signal will travel 10 Miles in that time. For a ghost
to be observed the original and the reflection must exhibit some
significant portion (or multiple plus offset) of that value. Let's
arbitrarily call your TV 10 inches wide and set the reflection with a
1 mile path difference. Thus the two images (original and ghost)
would be offset by one inch.

Now let's ramp that 1 mile difference down to a couple of feet (those
two adjacent antennas). You should then appreciate that 1 inch ghost
offset will shrink to sub mm (to mix units). Conventional TV
bandwidths could not resolve the difference.

Hi Gary,

By this, I suppose you to mean that any report of strikes to a tower were those chance occurrences of being seen as a direct hit, and no one regularly inspected all metal structures for evidence after a storm to verify unobserved strikes.

Hi Beth,

The reason why it is inspecifically cited as "practical" is that throughput is negotiated against distance and greater demand against a constant capacity. If you want to share the same resource with 33 times more customers, you have to accept 3% the bandwidth. Classic Cellular Telephone history. BPL couldn't possible keep up with terabyte demand, star configurations against fiber optic trunks will prevail.

I really get a hoot out of correspondence here comparing BPL to advances in science like Penicillin, when it is more like the legacy of Thalidomide. Folks thought that was a miracle drug too.

Let's do it differently: you point out single Cell phone, Wi-Fi or other consumer gadget that uses Fractal antenna. Point out any other application when the fractal antenna made difference.

What specific advantages you can achieve using fractal pattern? Increase bandwidth to some degree, make it a bit smaller - it can be done in numerous other ways. What else?

Let's turn to some empirics. Here is a website of the company claiming to be inventors of Fractal Antenna: Fractal Antenna Systems.
http://www.fractalantenna.com/

They were making them since 1998 I guess, have patents, all that. Look at the antennas (the antennas look beautiful, btw, like jewelry) - they can make it for any applications. Yet we do not see those antennas. And it does not look like the guys swim in money.

What does it tell us?

Andrey

Hi Richard,

Just so everyone is warned yet again, I personally would describe your site as a combination of non-attributed extant knowledge; trivial irrelevancies; and interpretations that do not follow from the data. It avoids any real info in extraordinary detail. Much of it is just plain wrong.

It is, as someone expert in the field, a poor source of info.

Knowing that you are eager for you and yours to be tied up in something bigger than a mere amateur's web site, I feel that I am most happy to back up those statements formally, meaning--why wait? Let it really be on the public record:-)? That way LOTS of people will see why my statements are accurate and that your agenda is, well, not motivated by the love of knowledge with regards to this subject

Your move, sport. It won't get resolved on a NG.

>>when the fractal antenna made difference.

Of course I could. But, even I can be convinced that a NG is not the site for commercial marketing, Andrey.

No reason to do it differently; I have invited you to make citations So...maybe I and others will learn something?

I will be happy to briefly discuss the technology and not the commercial products, however.

There is no question that in some single band cases, there are many different solutions that will meet a highly compromised need. The value equation in performance and cost, does, shall we say, benefit from the huge design space available with fractal antenna designs in other circumstances. That is, 99% of real needs.

The price of cell phone antennas has dropped from about $1.20USD to less than $0.09USD in the last 8 years. Let's say that in high volume (and for a given model, its actually not that high)the COGS is $0.06USD PU. Now pay the insurance premiums that the brain cancer litigation issue--an ongoing one, I might add-- adds. Suddenly, there's no reason to be in cell phones, unless you want to have a high chance of going out of business--as many antenna companies have; seems like one or two goes under every month or so. Obviously some folks want to continue to take that risk.

I'm not going to provide a list for you of products on this NG: customers, from my observation, want the emphasis to be on their product and not on a component in that product. I certainly know of applications in those markets you describe, in addition to emerging markets along those lines.

Of course, there is no reason why YOU can't spend some money and pop some tops.

Fractal antennas have made profound differences in the lives of many in the last few years, through their unique benefits in: smaller size; widebandedness; multibandedness; embedded/covert placement, control of observables; and so on. The early adopters have embraced the technology, and wireless commercial sector you allude to, after a very tough 2003, is coming back well.

So, you can see that the reality is very different from your statement. Or maybe you can't see that, in which case you should listen to someone who knows the reality.

I hope this helps. If you have commercial interests you know where to reach me off NG. Otherwise, it all goes outside of the scope of this forum, doesn't it?

73,
Chip N1IR

## 1014. Schematic Uniden UH040XR or UH042XR?

You can buy the replacement (missing) parts direct from Cushcraft...at least you could a few years ago when I odered some replacment parts for my 6M yagi. I believe there was a version simply called the Ringo (minus the Ranger part) which was just the antenna without any sort of groundplane radials. You might just try using what you have and see what the SWR is like and/or how well it works.

For 6M and 2M, see the website on the copper cactus antenna. I have one on 2M and they work nicely. See http://archimedes.galilei.com/raiar/cactus.html for plans for copper cactus antennas from 6M up to 1296 MHz.

For a 10M vertical, you could buy a CB vertical and shorten the vertical and radial elements a bit to tune it up on 10M.

I gave you no runaround, sir. No one knows who you are, based upon your insistence on anonymoty.

Professionals act like professionals and don't hide behind screennames.

I gave you the opportunity to take it off-line, and you have refused to do so.

So, let me offer you a second opportunity. Tell us who you are, and where you work, on this NG, and I will be glad to answer your questions here.

Randy -

Scott is partially correct.

In the early 1970's Cushcraft introduced the "Ringo" series (AR-xxx) for a number of VHF bands (10 meters, 6 meters, 222 MHz, 440 MHz) - both amateur and commercial (business band).
http://www.cushcraft.com/support/pdf/951284.pdf

The "Ringo Ranger" series (ARX-xxx) was developed a couple of years later. At first this antenna did NOT have the radials that you are missing.
http://www.cushcraft.com/support/pdf/951289.pdf

The "Ringo Ranger II" (ARX-xxxB) was introduced a number of years later (late 1980s) and this model added the Radial Ring and radials at a fixed distance below the Ranger.
http://www.cushcraft.com/support/pdf/951290.pdf

I would imaging that your Ringo Ranger never had the radial kit, because it is not a Ringo Ranger II. As Scott mentioned, you can purchase the specific parts from Cushcraft to convert your Ringo Ranger to a Ringo Ranger II (these part numbers can be found in the assembly / instruction manuals)

Cushcraft actually had a upgrade kit (specific parts as one order) in the 1970s and early 1980s -- for earlier Ringo buyers to "upgrade" their Ringo models to the Ringo Ranger model.

You're just digging the hole deeper, Cecil. I know you think you can use
the simplifications of transmission line theory to explain everything
in electromagnetics. Reg seems to think that's a valid way of doing
things, too. If it were true, it would certainly make life easier for
those poor souls who have to study Maxwell's equations in colleges
throughout the world. Just think, no more vector calculus for engineers!
From what I've read on this group the past few days, many engineers
don't learn it anyway, so why not just dumb things down to
your level? Maybe you should write a letter to Texas A&M telling them
they don't have to teach it any more. (If they still do, that is. Some
colleges have dumbed themselves down considerably in the past 20 years.)

Hi Richard

I was just a lowly sophomore peon in a class of mostly upperclassmen who had started the project a few years before I went to skewl there.

The project was a side assignment for extra credit that just seemed to carry on for all the years I was there and a few years thereafter.

I was an avid model railroader quite adept at building miniature structures to emulate their full sized counterparts.
This was my contribution to the project, the modeling end of it.
When a new building was built in the town, I would make a scale model of it for the project layout board.
I had to pay special attention to what objects of a structure consisted of metal components and how they were attached to the structure and if they led to a grounding source, as all of these factors played an important part in the experimentation that was going on.

I knew what the project was about and what they were trying to prove with it. But I truly was not that interested in the purpose of the project as much as I was in the authenticity of detail in the structures used on the project layout board.

In other words, I learned just enough to be dangerous in my observations, hi hi.....

However, the success ratio of known lightning strikes to the red zones on our layout board was phenominal.
The data was collected by a whole different team than the team I was on, but the layout board was loaded with bright orange lightning bolts glued to places of known lightning strikes and all but 2 of them were in our red zones.

I should note that a red zone was simply a 1/8 to 1/4 inch wide line drawn on for example, the edges of gutters, at certain elevations on taller structures not shielded by another object.

Naturally we did not know about many lightning strikes that did no damage or were not observed.

My own antenna farm has been hit several times, but never was their any damage because of it.

In fact, one year we had a strange phenomenon that caused neighbors to call the fire department on a couple occassions. One of my Yagi's appeared to have orange sparks flying from it, sometimes for as long

as a half-hour, but usually only for a few seconds or minutes. I was only priviledged to see this myself in person one time. Scared the bejesus out of me when I did too!

One of the firemen knew a man who worked on tall commercial chimneys or something like that and told him about it.
The many came to my house, checked a few things out, talked to a couple of neighbors and showed them some photo's he had taken of a similar phenominon on other structures.
Turns out what was happening was weather conditions and the charge in the air was just right to cause what was termed as St. Elmo's Fire, a phenominon discovered on old sailing ships at sea during a storm.

I lived in that house roughly 20 years and this only happened for one short rainy season in only one of those years. I had never heard of a similar occurrance to ham antenna's before or after this event.
And I've been licensed for 45 years!

Hi Jack

The damage to my tower was directly my own fault.

It was of tubular aluminum construction and DID have drain holes in the legs so they could not readily fill with water.

I made two very dumb mistakes that contributed to the damage.
The first was using one of these holes for attaching the ground rod strap to the tower, instead of the clamp that WAS provided for the purpose.
And the second was backfilling over these holes when a new air conditioner was installed, and a small retaining wall placed between the steps, tower and A/C unit.

Had there not been water in the leg of the tower, it would have taken the hit unscathed.

There was a grounding strap on each leg of the tower at the unions between sections, these were installed properly or should I say, per the instructions, hi hi.....

Ironic, I was way overboard on everything else as far as protection from lightning. Had a copper bulkhead on the house, grounded of course. All coax shields were grounded first to the bulkhead and then through gas bottles which were also grounded. The station equipment was ground, even equipment in plastic cases I installed a ground to the chassis and they were grounded too.

I did everything right except I forgot about one old abandoned rotor cable that was coiled up behind 4 file cabinets, out of sight out of mind. Luck of the Irish, the day I took the hit, I had sparks flying all over my shack. My pooch who was young then, terrified of thunder, came to my office to be by me for protection, just when the sparks began to fly. He never came into my office ever again!
The only damage from this rotor wire was a few burn marks on the back of the file cabinets. The tower obviously took the main hit.

As an aside. A tree outside my mothers home was struck by lighting. Split that sucker almost all the way to the ground. Dad bolted it back together with threaded rods and it survived, it's still living too.
But the reason I brought it up is that INSIDE the house, sparks danced all over my mothers stainless steel kitchen sink, made burn marks and pits all over it. We later discovered the aerator on her faucet spout was fused to the spout and it too was severely burned and pitted.

Back then all the waste lines to the sink were metal, not PVC as used today and all the water lines are copper. So I assume both the sink and the faucet were grounded.

Makes one wonder how lightning got inside the house and bounced around in her sink and did enough damage that the sink and faucet had to be replaced.

The transmission line model is more complicated than the circuit
model and works for transmission lines, including antennas, which
are single-wire transmission lines. Your overly simplified circuit
model doesn't work for transmission lines or for antennas. That's
what got you (and others) into trouble. All you guys can do now
to try to save face is sandbag and divert the issue.

Hi Mark,

And the intent in being obscure, or coy, is another marketing technique to churn a amateur newsgroup for commercial interest. When drawn into these banalities, the marketeer then steers the sucker through the maze of claims to elicit a public declaration "sure this looks good." Once having secured this admission from the prospect, the marketeer then has the leverage to ask "what is keeping you from giving me your money?"

All very standard and by the book [consult the recent activities of Mr. Spitzer, Attorney General for New York for other material found in "the book"].

Randy:

I noticed nobody answered question 1.

When the original Ringo was introduced, performance reports were all over the map. Some worked fantastically well,
others fantastically poorly. It was finally discovered the difference was due to mast and feedline radiation.
Sometimes the lengths were right to radiate well, other times, the antenna radiation was canceled by unwanted from the
support and feed. So, the radial kit was added. Four radials just over a quarter wave (20 inches seems to work well),
but I don't recall the exact position on the antenna. Just below the feedpoint seems right, but I defer to CushCraft if
you can get the location from the Ranger II manual.

From my time in broadcast stations, I can testify these conditions repeat.

In my experience, the radio towers took all the lightning strikes in the area.

Charge buildup was a separate phenomenon.from lightning. This happened in the wind ahead of an approaching thunderstorm. The insulated guy segments would charge from the static in the air, announcing the approaching storm with loud reports when conditions were right. Peering out at the antennas disclosed flashes across the guy insulators producing the reports. There were many towers with many insulators which produced barrage fire. Noisy!

This sounds like the most plausible explanation, especially since it used to
work. I would look for a bad connection at the antenna, or an F connector.

> The only damage from this rotor wire was a few burn marks on the back
> of the file cabinets. The tower obviously took the main hit.

A friend in Mobile, AL had several station equipments damaged this summer when protection was presumed to be "complete". Old cabling on the floor behind equipment racks was inductively charged and arced over to the equipment and computers, defeating the extensive surge protection installed. I had considered this a serious enugh problem to include it in a warning on my web page, and he was of course furious with himself about this since we had previously talked about it. This is also what I mean by the statement that lightning finds and exploits the weak parts of a system.

> As an aside. A tree outside my mothers home was struck by lighting.
> Split that sucker almost all the way to the ground. Dad bolted it
> back together with threaded rods and it survived, it's still living

> replaced.

Could be either from an older home's cold water pipe grounding, or EMI from the nearby strike. The former is more likely, when ground becomes saturated with HV from a nearby strike, it raises the potential of everything connected to it. Nowadays this is called "GPR" or Ground Potental Rise. Possibly one of the biggest causes of damage to stations that are otherwise "protected".

Tom Donaly wrote:
"I know you think you can use the simplification of transmission line theory to explain everything in electromagnetics. Reg seems to think that`s a valid way of doing things, too."

I had a graduate course in Maxwell`s equations, but had a long rewarding career without using Maxwell directly.

Reg is an advocate of Oliver Heaviside`s work based on Maxwell. Nothing wrong with that.

In his 1950 work "Antennas", Kraus has this to say about Maxwell`s equations:

"Maxwell`s equations are summarized in the tables. The first table gives Maxwell`s equations in differential form and the second table in intergral form. The equations are stated for the general case, free-space case, harmonic-variation case, steady case (static fields but with conduction currents), and static case (static fields with no currents). In the table giving the integral form, the equivalence is also indicated between the various equations and the electrical potential or emf, the magnetic potential or mmf, the electric current, the electric flux, and then magnetic flux.

Many texts do very well with no mention of Maxwell despite his contributions to electromagnetics. That`s too bad, but that`s the way it is.

Best regards, Richard Harrison, KB5WZI

Are you trying to make some point? If so, I'd sure like to know what it is. It appears you're trying to pretend that the gradient (a mathematical term) in the standing wave current along the length of a radiator doesn't exist. Why? It's a very simple and straightforward notion.

Wes,

You demean a scientist merely to
feed your perverted ego and maintain
your narrow-minded preconceptions?

Where is the intellectual honesty in
that? Where is the science in that?

You demonstrate the only kind of
science you support is that which
confirms your silly preconceptions,
despite reality.

Which would imply, had the
comparison gone the other way,
you'd have accepted that data
unquestioned.

Hypocrisy has no standing in real
science.

Sheesh, how stubborn/bull-headed are you??? If my customers had to go thru this much to get info, I would have closed down years ago. You have my email addy...just send the bloody info. All I have asked for is info on who is using mandelbrot ("fractal") style antennas in a commercial application which can be accessed either via the 'Net or via literature which can be requested (i.e., a company which is producing such antennas for commercial sale).

You misunderstood me. I didn't mean the reflections from the antennas themselves. I was talking about reflected signals picked up by the off-axis 'main' all channel antenna. Of course, for the reflections to occur, there would have to be some geographical or architectural feature for them to reflect off of. In my neighborhood (near center of a metro area), rooftop antennas have to be rotated for each individual channel. Many times, the optimum direction is more a function of achieving fewer ghosts than aiming directly at the station.

OK, so if I understand you correctly *any* splitter can work as a
combiner?

If so, do you have an idea why the following splitter is *not* labeld
as a combiner: http://tinyurl.com/kzr2, while the following:
http://tinyurl.com/6k5a9 is labled as such?

> The problem is that since the bands of use are similar you cant stop
> (say) the FM omni receiving some signal from the TV band transmission
> appearing at the input to the TV. This will most likely cause ghosting
> or other degradation.
>
> I suspect that you mean unidirectional VHF/UHF antenna rather than an
> omni. Using an omni is very likely to also create TV ghosting.

I didn't initially mean that (since I was hoping to receive more than
one station), but now that I read your explanation I have to accept
your suggestion. In fact, my current setting is a single
unidirectional FM/VHF/UHF antenna (http://tinyurl.com/52tjr) in my
attic, but because the space in the attic does not allow using a
rotator and because I have only one coax arriving to my living room, I
need some creative solutions to achieve the goal of having both the FM
and TV antenna signals arriving on a *single* coax to the living room
(afer which it can neatly be split behind the entertainment center
furniture).

> You could conceivably notch the output of the omni to not pass TV
> signals but by now the project is getting kind of expensive.

I don't mind spending a reasonable amount of money on a good solution.
Do you happen to know of such products (that would filter out TV

signal)?

> I suggest you just use the one TV unidirectional antenna and have a
> single splitter inside the house connected to the FM radio and TV. You
> may get sufficient FM signal for your needs.

Currently this is indeed the situation, but because the antenna is
unidirectional, I can only receive certain FM radio stations - and I
miss some important (local) others. I find this unacceptable given the
fact that even my poor kitchen radio can receive all local stations
pretty well with a simple built-in whip antenna... Hence my idea of
installing an omnidirectional FM antenna in the attic and combining it
with the TV signal for the single coax.

BTW, if an omnidirectional TV antenna is *always* a bad idea because
of ghosting, how come such antennas are offered on the marketplace at
all? (such as the Winegard MS2000:
http://www.starkelectronic.com/wms2000.htm)?

> Cheers Bob VK2YQA

Hi Art,

Ok, I'm always open minded to learn
something new...

I'd like to establish a few things, though.

First of all, what modeling program are
you using?

Is your empirical data consistent with
the models?

How are you ascertaining your empirical data?

How are you determining the current amplitudes: By model? Or empirically?

And what are the machinations that demand ultra-thin wires to establish the gain?

You can email me if you care to not discuss these things in an open forum.

Not only have been told, they wish not to be identified and agreed with the approach, as they're more interested in viable/available technology....the European company is under the same conditions (and it turns out that they have been following these exchanges).

## 1061. (OT) BPL Alternative

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-21 19:18:39 UTC
From: Jim <IHateSpam@NoSpam.net>
Message-ID: <bYTdd.184$mf7.161@fe39.usenetserver.com>
Source record: 87856

There has been some discussion here on the pros and cons of BPL.

I thought I would through in my 2 cents worth...

Why doesn't the FCC 'suggest' that cell phone and PCS companies install some type of WiFi node at every cell site in the country?

A few questions on this: What percentage of homes have a computer? What percentage of those use the internet regularly? Of those, what percentage would use DSL or cable modem (if available)? If WiFi was available everywhere, how much would it have to cost in order to even break even?

Jim

I think this Fractenna guy is ... ? ... or something. He managed to argue here with everyone who asked him questions.

Now, does he really represent Fractal Antenna Systems?
http://www.fractalantenna.com/
All the patents mentioned on this Website have single author: Nathan Cohen.

If that's him and he makes all this noise on behalf of his company (pretty unrealistic assumption anyway) ... this is not a good way to market innovations, be it fractal antennas or anything.

They may be good innovations then, just hindered by his approach.

Andrey

PS: If someone has commercial request for Antenna design, I can help too - I do it for living. No fractals, just whips, patches, dipoles, loops, arrays - everything from the classic books. I am an older guy. And of course, matching, tuning, conforming and any sorts of customization. I have several patents too, though I do not think of them as anything special.

"Drawing gain curves is a fun activity...but don`t try to read too much into them."

I searched on "yagi boom". I got many responses. One showed Ian as the custodian of a computer program to design yagis. Another was from the Central States VHF Society and gives results of their 2004 gain comparisons of many different antennas. Gain of these versus boom length looks very ragged.

Best regards, Richard Harrison, KB5WZI

> Ok, I'm always open minded to learn
> something new...

Wow,,,..... there are not many people around who could say that !.
Since 99.999% of things presented as new are incorrect most experts
have determined that the odds favor them if they label EVERYTHING
new as in error. If something comes along that is really new they always
have the comment ' I knew about that a long while ago" to fall back on.

>
> I'd like to establish a few things, though.
>
> First of all, what modeling program are
> you using?

Beasely AOP
This is the professional version that has more than enough segments
and variable dimensions available to lesson the chances of human input
errors
plus to handle elements that were in close proximetry to each other,
together
with 'Sommerfield ground' handling capabilities.

>
> Is your empirical data consistent with
> the models?
Not measured, my thought were that NEC would always
be closer than field measurements generated by an amateur.
>
> How are you ascertaining your empirical
> data?
>
> How are you determining the current
> amplitudes: By model? Or empirically?

By model,
The program provides % of max current at every segment,
phase and all that good stuff

>
> And what are the machinations that
> demand ultra-thin wires to establish
> the gain?

Go for 80 % gain and the rest (20% ) for swr
Added half a dozen elements
All dimensions variable except boom length and perfect ground height
Remove one element at a time until max gain point is obvious
Note all dimensions are kept variable at all times.
>
> You can email me if you care to not
> discuss these things in an open forum.

Not necessary, This is the very reason I posted in the first place !
The program shows that the normal 2 element is not the optimum
in that a polygon of vectors beats a triangle of vectors.
At the same time with added elements you get diminishing returns in std and
conventional forms.
The program showed that 1 to 1.5 dbi was available over the standard
2 element on the same length boom.if one could overcome mechanical
restraints.
(I was comparing to a Beasely example of what gain could be attained for two
elements on a 7 foot boom)
Now that is not the end of the experiment as I cannot verify the accuracy of
the program,
because I did not write it, and I certainly cannot say that my modelling
aproach is
without error since that is what many 'experts' point to if they don't like
the results.
It was for that reason I asked if any similar data had been made available
for boom length
by reputable programmers and antenna 'experts' for comparison purposes ., If
these initial
results were quoted as accurrate there would be howls from all the resident
antenna ' experts"
and I would immediately be placed in the six foot hole that they have been
trying to put
you in for the last eight years

Gain vs. boom length makes sense only when comparing or tracking the same antenna design i.e. Yagi with multiple elements. One can design lousy antenna on a long boom.

Jim Lawson, W2PV was one who after some modeling showed that gain in the properly designed antenna is roughly proportional to the boom length rather than to number of elements. Some manufacturers "beefed up" their antennas by sticking more elements on the same boom claiming better performance.

Guess what Andrey... that company was founded by Nathan Cohen. And Fractenna
has been signing his posts as Chip, N1IR. An ARRL call sign search turns up

COHEN, NATHAN L, N1IR (Extra)
(address withheld)

So I guess you're right. He has a vested interest in arguing for fractal
antennas, yes?

John

Yes but I believe that the early computorisationd he used was based first on
mechenical designed elements which were then imputted.He did not mess with
the element diameters after that.As an aside if you densly populated a boom
with elements many are put off by the low impedance being totaslly unaware
that an additional reflector an up the input impedance back again......
another example of what coupling can do for antennas

"Richard Clark"
> If you want to share the same resource
> with 33 times more customers, you have
> to accept 3% the bandwidth.

Excellent point.

Of course, to start, they could put up one site and let it evolve from there. 56Mbps / 33 is still 1.7 Mbps (perfectly acceptable). Even 333 clients is still much better than dial-up. Also, those 333 clients probably have other things to do beside 100% downloading music and p0rn, and so you can add a huge (or 1/huge) duty-cycle factor (worse at prime time). In other words, one 56Mbps access point is capable of serving MANY clients (a wireless MAN). The future dividing into smaller cells is a nice bonus that can be paid for with cash already earned from the first installation. Thus Wi-Max is going to be ~huge~ because the finances are incredibly good (waaay better than cell phone since the sites are going to be soooooooo much cheaper, one or two orders of magnitude cheaper, a guess).

BTW, if the 'last mile' is such a big problem, then how come the Cable TV companies are so damn rich? Duh. Run the damn optical fibres and 'clean up' the whole market for fixed access. Nothing beats optical (so far).

Didja see the 'interesting tidbit' about non-HF 'BPL' ? Sounds much nicer than the HF-crap system.

> every cell site in the country?

It's called Wi-Max (IEEE 802.16a) - it will have the range to do as you suggest and YES THEY WILL do exactly that without being asked by FCC. They're probably biting their nails waiting for Wi-Max to be 'actually available' as opposed to 'coming soon'. Probably two years - it'll move ~very fast~ once it is started.

Wi-Fi doesn't have the range unless the user installs a very high gain antenna. Some cities are installing Wi-Fi into (almost) every lamp post.

CG & Randy -

Correct about the Ringo and original Ringo Ranger performance reports --
some lamented that it was the best dummy load Cushcraft ever built !
I liked mine, and actually used a Ringo Ranger at 200 feet hung upside down
(for proper radiation pattern) for a repeater's transmitting antenna in
1976 - with great results. We replaced it 2 years later -- with a heavy
duty commercial unit (that could take the wind abuse).

The Ranger II has a coax of specific length between the radial ring and
Ranger -- so that the distance of the radials is correct. This is covered in
the Ranger II manual.
http://www.cushcraft.com/support/pdf/951290.pdf

So, you have a standard Ringo Ranger and you can purchase the parts from
Cushcraft - IF you desire to upgrade it to the Ranger II model !!

> ft up. Is there a way to determine the tower type?

Check the detail dimensions of the center-to-center distances between
the legs given in the links.

20G = 12.5" CC with 7 horizontal elements
25G = 12.5" CC with 8 horizontal elements
45G = 15.75" CC
55G = 18" CC

> I thougt it would be relatively easy to do this from a bucket.. Come
> along side, unbolt it. then go above and lower it with a rope?

It's not a simple disassemble and drop process. 99% of the time the
sections have to be jacked apart often via considerable force due to
misalignment and corrosion effects. Particularly if the tower has been
used for a number of years as it has in your case.

At the instant the topmost section finally pops loose from the next
section down you'd have an unmanageable 10 foot long pile of steel by
it's bottom end wavering in the wind over you in the bucket. NO
THANKS! And it gets worse if it's an R45/55G tower with it's much
heavier sections . . etc.

The normal procedure is one man up the tower and belted in doing the
wrenches and the jacking while the section being removed is tensioned
upward via a gin pole (portable crane, Google it) controlled by his
helper on the ground. Who lowers the section to the ground after it's
off the the tower.

Tom Donaly wrote:
> Who said anything about a circuit model?

I'm going to present an example, step by step. Please contribute
something technical in response.

It's a simple lossless quarter-wave matching section example.

------50 ohm feedline---+---1/4WL 600 ohm feedline---7200 ohm load
Pfor1=100w--> Pfor2=352w--> 100w
<--Pref1=0w <--Pref2=252w
Vfor1=70.7v--> Vfor2=460v--> Vload=849v
<--Vref1=0v <--Vref2=389v
Ifor1=1.414A--> Ifor2=0.766A--> Iload=0.118A
<--Iref1=0A <--Iref2=0.648A

Vref2 is 180 degrees out of phase with Vfor2 and thus they subtract.

Iref2 is in phase with Ifor2 and thus they add.

The impedance at '+' is (Vfor2-Vref2)/(Ifor2+Ifor1)

The impedance at '+' is (460v-389v)/(0.766A+0.648A) = 70.7V/1.414A = 50 ohms

Note that the impedance seen at the match point is:

Vfor1/Ifor1 = (Vfor2-Vref2)/(Ifor2+Iref2)

So Tom, do you find anything wrong with this network analysis? If so,
please be technically specific. (Sorry, your feelings don't matter.)

Ever read the Rhon ad in QST? The one that warns you about climbing used towers that may not be in very good shape? It used to be in the back of the magazine and was really not an ad, but an FYI on the dangers of taking down a tower. Partly in their own interest, no doubt, related to potential lawsuits.

The dingbat wants your ID so that he can send you a laughable (but annoying) threatening legaleze mumbo-jumbo e-mail. It is much more relaxing to taunt the lunacy from a slightly more annonymous position.

The dingbat has one valid point. There are nearly infinitely more 'fractal' shapes than simple shapes. This means, as he says, that the solution space is vastly increased by using fractal-shaped antennas to provide some weird combination of parameters.

What he won't acknowledge is that there are *infinitely again* more non-fractal squiggly shapes than pure fractal shapes (turtles upon turtles all the way down). Therefore, his patents are apparently worthless because, even if there were some applications that happened to 'allow' a fractal antenna solution, anyone could take the fractal antenna solution and randomize it a bit (loop until better) to make it slightly nonfractal (and better at the same time!) and off you go.

It must be annoying to have spent the entire bundle on this and only now realize that it is absolutely trivial to walk around the patents.

That would be if, big if, anyone cared to.

I hereby place all slightly non-fractal squiggly antennas into the public domain.

The poster needs to find a ham radio operator who lives nearby who can help him. Most hams have a reasonably good understanding of antennas and could probably find the problem in 5 minutes.

About 15 dollars a month is what they are charging in Chaska MN, and that will allow them to maintain the current system as well as store a bit of cash for new equipment when they need it. The customer base was over 2000 last I knew, and 2 years ahead of what they expected. The charge includes everything including customer premise equipment.

They are using 802.11b, and each customer gets approximately 1.5Mbps throughput, except for one of their coverage areas which they are having a problem with. That one still gets something like 500Kbps, which isn't bad. The billing is done through the city water bill, so it's quite convenient, I would guess.

The equipment is Tropos, which we examined, and it is about as bulletproof as you can get. They (Tropos) use a Loctite type of substance on the 6dB gain omnis at the factory, so they don't leak or come loose. Seems excessive on an N connector, but definately thorough. They have heaters in them to keep them warm enough in the subzero winters. They can be mounted antennas up, or antennas down by reversing the outside case. And a nice touch is they use a sandwich plug for power that plugs in at the light sensor on a streetlight. Takes about as long to get the bucket truck in place as it does to mount and get it running. They need virtually no configuration on any individual unit. Runs as a mesh network; in their case, multiple mesh networks.

And nope, I don't live there, but my company visited to see how they did it, etc. Don't have any affiliation with Tropos, either. We use the Motorola Canopy Product.

Their web address is www.chaska.net

For VHF/UHF yagis in free space -

WA2PHW Gain Figure of Merit

G = 10 log (5.4075 B + 4.25) for B GT 1

Where G is gain in dBd and B is boomlength in wavelengths.

This is from a database of over 100 VHF/UHF yagis compiled in the early 90's. These are all real buildable yagis, and the antenna range numbers closely agree with the computer models. The numbers were heavily influenced by the 10 to 40 element K1FO series. Thanks again Steve.

Note that this predicts a zero length yagi should have about 6 dBd gain. Any ideas on why it intercepts there?

What? Of course it means something. It's an equation along with the
constraints.

Run any current decent 1 wavelength, or longer, yagi in your favorite
modeling program, and it will tell you whether you are near the gain you
should get for a well behaved yagi. Or it might tell you the model
isn't very accurate. It works well to test known designs against
unknown quality programs without having the known good modeling program
or test range.

If you want the database it was derived from, that might be arranged,
but it is in from a database program that Microsoft Office won't read,
so you might be out of luck there.

Hi "John",

I have a vested interest in the accuracy of my comments to Andrey, which he solicited.

What's YOUR interest, :"John"?

No one is selling fractal antennas on this NG, John.

My motivations were to take the commercial stuff off-line (hardly a hidden agenda) and to counter hi targeted statements with some relevant fact and query on his supposed sources. his was apparently to introduce commercial interference.

I imagine that some person on this NG with his head in the sand doesn't know who I am at this point--but I doubt it.

I am amused, however, to have you think that I am so unwilling to 'fess up to my background. See, for example:
www.qrz.com

Do a look-up on N1IR. That's pretty transparent.

Are you expecting me to feel put-out in some way by these histrionics?:-)

Anyway, don't do this purely for my enjoyment:-)

Hi John,

Your information is incomplete. The records at that time described it as a small extension campus largely devoted to Home Economics studies. There could be some confusion about just who you have researched however. Some years ago we had at least half a dozen "personalities" all writing from this account or claiming to be different individuals (or the same individual, it was hard to tell).

One common modus operandi was in (their/his/her) attempting to build a data base by cultivating personal and business information in this group, then sending harassing correspondence. If there is any doubt about who/what/when/why the archives are choked with this Soap Opera. Simply Google search the newsgroups with terms: "suit," "our lawyers," "your lawyers," "cease," "copyright infringement," and the ever famous "protected by patents pending." Correlate these terms to recognizable authors and all should come into resolution. :-)

Boy, I've met some goofballs during my days with the Voter's Drive. Makes this stuff seem like a tired retread - wait! It IS a tired retread.

> The poster's screenname says it all...

I presume that you meant 'e-mail address' vice 'screen name' (assuming that you aimed at the obvious target, and missed).

The screen name ("Le plume de ma taunt") is actually hilarious - I hope that the humour wasn't wasted on you. 'taunt' vice 'tante' - get it? Ah, forget it.

Now, go away, or I shall taunt you a third time...

Hi Barb,

If they are so damn rich (arguable proposition given how many times
mine has been traded), it was from an investment now 20 years old.

If someone took the plunge and hooked fiber optic to every house in
the city, I am sure they would be damn rich in 20 years too. Problem
is with regulation. It existed then, it doesn't now.

BOTH the democrats AND the republicans walked away from the problem 6
years ago to leave it up to "market forces." This was like tossing
money at street bums to help them sober up. The corporate welfare
state stumbled along content with the status quo, happy to sew up
their constituencies knowing competition had a huge energy well they
had to climb out of to simple enter the market.

However, this also reveals the poverty that exists in the minds of
these welfare queens. They think in terms of their own solutions -
wire to the house (or fiber optic to the house). Not looking any
further than their own preconceived failure, they presume everyone
else will fail similarly. This dinosaur mentality reveals itself in
the BPL "wiring" opportunity. RF will eclipse their Jurassic ideas
and they will demand an "even playing ground" (familiar cry of the
entitlement addict) as the mammals gnawing on their ankle bones start
to work on their haunches.

We need to outsource more boardroom jobs to those with quicker minds
willing to actually work harder to be more productive for less.

Tom, let me be direct without being disrespectful What I modelled was a boom length of 7ft for 20 metres and it is an abnormal yagi design which does not fit what you are offering. I do not believe that NEC programs vary too much on standard forms but when using tightly clustered elements on a short boom lots of other things come in to play, and one has to be sure that the program is all encompassing as designed to handle ALL abnormalities. Obviously what you have offerred has serious problems on short yagi's let alone abnormal design yagi's. It is my belief that because an element reradiates
a portion of the RF that it received, extra elements that are closely clustered can provide increased gain. Yes. my model
confirmed that but I was hoping that experts could point to a mathematical analysis of max gain per unit length that was exacting in gain provided and not "close enough" and not marred by other things that can occur by measuring in the field.
It would appear from the responses that efforts in this area has not been undertaken and which I will have to live with that.
But I do thank you for your offering
Art

Hi Richard

Now 'that' I have seen a few times.
Probably not to the extent that you have experienced though.

When first out of skewl I took a job as a DJ, before a couple of storms while working in the transmitter room at the tower site, I could hear occasional pops, but never figured out where they were coming from. Thanks for letting me know!

From my new residence I can see several radio and TV towers, I will keep an eye on them just out of curiosity sake.

Hi Jack

That was probably the cause!

I figured the sink itself was at one ground potential and the faucet at another which caused the arcing.

Of course, the way mom described it, one would think the whole sink was ablaze.
Even back then I thought of possibly a single drop of hot metal (probably from the aerator) and how that is what probably bounced around in the sink sparking all over the place. Like dropped hot metal when your welding goes all over the place.

Speaking of differing ground potentials. I think the wierdest thing I ever saw was when my step-son was taking me through the automated welding section of a body assembly plant for cars.

A line of steel platforms bolted to a steel floor framework, between two of the platforms (about 2 to 3 inches apart) there was an occasional arc that occurred when the machines on each both stopped at the same time.

Don't know if you remember the old vacuum powered windshield wipers that operated independent of each other. Every once in awhile they would be in sync for a few wipes.
When these welders came into sync they hummed really loud and when the sync broke is when the arc would jump between their two stands.

I thought it was interesting!

Hi Richard

Are you insinuating that a tree struck by lightning cannot live after being electrocuted?

Although not logical, since the sap turning to steam is more than likely what split the tree in the first place. The path to ground could have been less than 1/4 inch wide on opposing sides of the tree.

Nonetheless, the tree is still standing. It does have some strange areas of bulging bark where the crack used to be.

I don't remember the exact year of the strike, but it was after 1968 and before 1972 and now this tree is the larger of the pair in moms backyard. It's immune system must have been damaged, because it has suffered from galls ever since shortly after it was split.

Now, as far as bolting trees back together using threaded rods, this is not uncommon at all. The forked maple tree in my own front yard at my St. Louis QTH was bolted together in two places to keep the two trunks from spreading further as the tree grew. It worked!
A cedar tree in my backyard that split during an ice storm was mended the same way at the same QTH. On this tree you can still see a part of some of the rods that were used.

It only takes about 3 to 4 years for the large washer and nut to be covered with bark and depending upon the gap where the rods were placed, they may be visible for decades or covered in short order.

Denis -

This specific antennas has been discontinued by MFJ / Hy-Gain. An Adobe Acrobat version of this manual is available from the Hy-Gain web site.
http://www.hy-gain.com/products.php?prodid=AV-18AVT

http://www.hy-gain.com/man/pdf/AV-18AVT.pdf

Although the original manual did not have the length of the 4 radials below the 80-meter resonator, I did see that on Page 6 of the Adobe Acrobat document -- that someone had handwritten in this data:

1/8" solid rod -- 11 1/4 inches length.

Possibly an actual 18AVT owner could confirm this handwritten measurement.

Lefty wrote:
"How many realize the ARRL is a business?"

Of course it is, and it is operated by and for its small group of insiders. As the only significant representative of licensed amateurs, ARRL is a monopoly which enjoys the benefits of its status.

Someone must have shown the insiders that deregulation would increase the ranks of amateurs and potential revenues to the ARRL. Now, ARRL is ready to lobby for deregulation. The FCC has been on its path to consolidation, simplification, and deregulation for many years. The FCC should be encouraged to accelerate deregulation. It allows more citizans better use of a valuable public resource. The public owns the radio spectrum. Only enough regulation to assure interference is held to acceptable levels and that common carriers as natural monopolies don`t abuse the public is desirable.

Washington,D.C. needs an Elliot Spitzer who would successfully investigate government agencies and the interest groups who lobby them. Daylight on the deals between the D.C. players might lead to needed reforms.

Best regards, Richard Harrison, KB5WZI

## 1119. 1200 and 2400 MHz antenna design

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-22 15:16:23 UTC
From: Mitchell <mingram1234@alltel.net>
Message-ID: <ev9ed.3$xk5.0@fe39.usenetserver.com>
Source record: 87814

Looking for a design for a multi-element (10-20) yagi antenna that I may use for sending/receiving wireless audio/video used for surveillance system.
Not having the best of luck finding same at this point.
Any help for one's already designed or a good formula to go by to build my own.

Thanks,
Mitchell

# 1120. Re: Discone antenna & antenna tuner?

Newsgroup: rec.radio.amateur.antenna

You say it covers from 28Mhz to 500Mhz. The one I am familiar with that does this is a modified discone that acts as a 1/4 wl antenna with ground plane at 28(probably 27Mhz) If this is the antena I am thinking about it has a long whip coming out of the cneter of the disk and 3 or 4 extra long radials in the skirt. These antennas worked on 144, 220, 432 bands with reasonable SWR.

No appreciable difference between them and NEC program results. You can build every bit as good of an antenna using the curves and given formula as you can a NEC program. Optimization of antenna built from either data still requires the same cut and try tweaking to get the last .001 db out. For all practical purposes the ARRL curves are as good as any. Obviously you have some impractical uses in mind.

Your stilted language is difficult for me to understand, Richard.

To what account are you referring?

Do you mean the association of Cohen to Fractal Antennas to N1IR? It is a coincidence that a person who uses the screen name fractenna and signs his posts as N1IR happens to have the same name as the person who founded Fractal Antenna Systems, lives in the same area, and vehemently supports fractal antennas?

John

The TV-5 antenna is an angular figure 8 in the horizontal plane having
an overall span of 64cms but measuring around the fig.8 periphery is
86cms. In order to give ~ 8dB gain I was proposing to place 2 directors
in front of the fig.8 and a reflector behind with 0.15 wavelength
spacings and was seeking comments on the idea.

I get the impression that what you are doing
is placing any number of elements on a .1
lambda boomlength, in order to determine if the
close proximity EM interactions produce more
gain than just the standard 2 elements would
on that same boomlength.

In the optimization process, some of the
resulting element diameters are quite small.

You're asking if anyone else has looked into
this, and if any results have been published.

Is this a correct assessment so far?

Cecil, if I had a dollar for every time you challenged someone to solve a quarter wavelength transmission line transformer problem I could eat a meal in the best restaurant in San Francisco and still have change left over to pay a 20% tip. The question is not whether or not the theory you made up in your head is right or not, but whether the length, shape, volume, whatever of a loading coil on a short antenna makes any substantial difference in the efficiency of the antenna. The problem of increasing the total current on a short antenna was solved so many years ago the fellows who solved it are old enough to be Richard Harrison's grandparents. If Yuri would spend more time researching his subject and less time with his fish thermometers and his diatribes against Tom Rauch he would learn that.
73,
Tom Donaly, KA6RUH

Tom
You would have enough money to own the restaurant.

sigh
Here goes---
Any difference in current between the ends of a compact loading coil in the
center of a short whip is due to radiation from the coil.
The same people have been making the same arguments here for years.
sheesh!
OTOH is has been entertaining.

Hi Richard

My gut feel is that adding elements to a set top antenna is a pointless exercise. I think your biggest problems to obtaining a sharp low null pattern wil be internal (room/building) reflections and detuning by being close to other objects. (Element detuning will affect gain/nulls and as soon a you walk near it or place it within a few metres of any objects it will affect the pattern badly) The elements will also lower the antenna input impedence. This may or may not be a problem to the following amplifier.

I am suprised that with transmitters that far away (I guess 50 miles not 50 metres) you are even considering using a set top antenna. I assume you have a good reason for this so there is no point embarking on suggestions of an external one.

If I was limited to using an internal antenna I'd make a 3 element yagi specifically for 187MHz and tune it for maximum front to to back. Given the bandwidth of a TV signal though I doubt I'd reach a good figure. I would follow this by a preamp also tuned to 187MHz. Even then I doubt I'd get pleasing performance with it internally mounted.

The only other suggestion I can make is to go ahead and try it and report back to the NG. Keep in kind that you have to do a good job of tuning the elements you add (spacing and length) to get good nulls. You may in fact want to try a single quad loop reflector and add a air space tuning capacitor in the loop. The idea is to resonate it to about 5% higher than the operating frequency so you'll need to make it slightly larger than that again to allow for the capacitor.

I apologies for not being much help!

Cheers Bob VK2YQA

Registering with party affiliation is only relevant for party
primaries.

In some states, you must be registered in advance with a political
party in order to vote in their primary election. In others, you can
be unenrolled, walk into the primary and choose a part, vote, and then
go back to unenrolled on the way out.

For a final election, such as November 2, everyone in your district
gets the exact same ballot, so party affiliation is irrelevant.

Some will automatically vote for their party's candidate.

Some will vote for the one with the best hair, or the one they would
most want hang out with, or the one with the best slogans.

Some will learn about the important issues, understand the candidates
positions and track records on them, and vote for the candidate of

whichever party they feel is best qualified and will best represent
their personal views and the best interests of the American people
going into the future.

Happy trails,

Close element spacing was once used to make a class called supergain antennas. Kraus notes in his 1950 "Antennas" that: "Until the antenna power was considered by G.H. Brown (Proc. I.R.E. January, 1937) the advantages of closely spaced elements were not appreciated." The W8JK array by Kraus is closely spaced. Kraus notes a downside: "Hence, a considerable reduction in radiating efficiency may result from the presence of any loss resistance, (The radiatiation resistance drops as spacing shrinks.)" See "Antennas" edition 3 for close spaced antennas.

Jonathan:

Well, I usually point out the dangers, but these other replies are all over the map and typically misleading. If you
have a 50 foot long clear area, and some competent help, send one person up in the cherry picker. Raise it to about 90%
of max height, and tie a short rope to the tower. Then, jack apart the lowest joint, while keeping the slack out of the
rope. If the bottom section is buried in cement, torch it off at the ground instead. With a little care, there will be
no sudden changes in loading on anything. When the tower is loose, walk the bottom away from the base while the cherry
picker lowers straight down. Then do the remainder of the disassembly at ground level. Be sure the cherry picker is
rated for the load, and the outriggers are properly set.

Source record: 87733

I have the Comet UHV-6, and the instructions don't say how it should be tuned (sequence, etc.).

It has 440/2 meter/6 meter in the basic configuration, and I am having trouble getting the right swr on it, I have an swr meter.

Could someone tell me which sequence should be used?

Thanks for any help,

Estel J. Hines

>
> Randy ka4nma

Randy, I was once give a Ringo with the hairpin match and top part.
It had been through several typhoons and such. Anyway, I couldn't get
it to match as designed, so I gave it away. The ham I gave it to
threw away all of the extra stuff, and just used the bottom half of
the antenna and the ring "o" part. Worked great.

Don't give up if the radials are missing. You might be able to use
just the bottom half.

No, that's not the question at all. You have diverted the issue from current through the coil to efficiency. The question is whether the current at each end of a real-world loading coil is the same or not the same. Efficiency is irrelevant.

Diverting the issue is an obvious tactic employed by someone who is losing the argument.

If one doesn't understand standing waves on a transmission line, one cannot understand standing-wave antennas. The ignorance of how standing-wave antennas work is the basic problem. I am attempting to alleviate that ignorance.

H. Adam Stevens, NQ5H wrote:
> Any difference in current between the ends of a compact loading coil in the
> center of a short whip is due to radiation from the coil.

That's an old wives' tale. But don't feel bad. Kurt N. Sterba made essentially that same mistake in his Nov. 2004 article in "Worldradio". Anyone who believes that the current is zero at the tip end of a standing-wave antenna because it has been radiated needs a refresher course in standing waves.

**********
* Any difference in forward current between the ends of a loading
* coil is due to radiation from the coil.
*
* Any difference in reflected current between the ends of a loading
* coil is due to radiation from the coil.
**********

Please read those two statements until they soak in because they agree with you about component currents but disagree with you about superposed currents.

The main difference between the net superposed current at each end of the coil is caused by the phase shift through the coil acting on each of those current components in opposite phase-rotation since they are traveling in opposite directions.

Is any difference in current between the ends of a section of transmission line due to radiation from the transmission line? Yes, but most of the difference is due to phase shifts between the forward and reflected waves. Exactly the same concepts apply both to a transmission line with standing waves and a standing-wave antenna. In fact, a horizontal wire antenna is nothing more than a "lossy" transmission line losing energy to radiation.

A mobile antenna is a standing-wave antenna possessing a Z0, just like a transmission line. There's a forward current and a reflected current. The superposition of those two component currents causes the main difference in the magnitude of the net current at each end of the coil.

When Roy, W7EL, measured the phase of the current at each end of the coil, he measured the phase of the NET superposed current, not the phase of the forward current or reflected current. The phase shift of the NET superposed current is only a couple of degrees max from feedpoint to end as asserted by Kraus in "Antennas for all Applications", page 464.

In the ARRL Antenna Book is an equation for the characteristic impedance of a single wire over ground. It is 138*log(4h/d) where 'h' is the height of the antenna and 'd' is the diameter of the wire. The Z0 for a piece of #16

wire positioned 24 feet above ground is about 600 ohms. A quarter wavelength of that wire used as an antenna responds essentially the same as a quarter wavelength of lossy transmission line. There is a large reflected current component at the tip of a mobile (standing-wave) antenna.

In fact, my earlier quarter-wavelength matching section plus its 100w load acts similar to a quarter-wavelength antenna radiating 100w.

If you decide to buy, check out http://www.directivesystems.com/ . Some of their stuff is also available from Down East Microwave. For abour $100 you will get one with about twice the number of elements you mention. At these frequencies all your dimensions have to be very exact. I once bought their big 2.4 GHz loop Yagy.

Today I made up a 2 director, 1 reflector "beam" out of 1/4" dowels
wrapped with cooking foil, the reflector was planned to be 26cm to the
center of Terk dipole, Terk to 1st director is 16cm as is 1st to 2nd
director. The reflector is 80cm, 1st director is 73.6cm, 2nd director is
71cm. It appears to make a big improvement, however it "works best"
positioned with the Terk about 2cm behind the 1st director! I have no
field strength instruments but though "snowy" the sound is quite solid.
I have not yet tried moving the whole assembly around the condo living
room though given the Terk amplifier I should be able to use several
meters of coax before the loss starts to show in noise figure.
The "Association" does not allow external antennas and as I watch very
little TV I resent paying $50/m for the one or two hours I watch each
month. I am a retired microwave device engineer but not an antenna expert.
Thank you for your interest in my experiment.
Dick

Hi John,

Historically, there have been MANY authors, all making claims to be different persons OR there has been ONE author claiming to be different persons FROM ONE account that is not a professional address. ALL supposed authors claim to be working for a commercial business selling fractal antennas. However, this is strictly speculation as absolutely no evidence of this commercial pursuit is apparent in ANY correspondence.

Stilted or otherwise, the confusion resides at one common point originating these messages. In just the past week I've seen several messages posted by two sides of a dialogue BOTH claiming to be the same correspondent from different addresses. Signatures at the bottom of a post are a wholly insecure means of asserting identity. Further, individuals attempting to draw you into commercial correspondence through non-commercial addresses (accounts) are the leading form of Phishing. I hope this last term is not lost on you.

Cecil, I'll believe you know something about loading coils when you
go back to school and learn something about basic classical
electromagnetic theory. As it stands, all you can do is make one
unsupported statement after another and hope someone is gullible
enough to believe you.

If the radials are to decouple feedline radiation, then why wouldn't coax coiled into a choke balun work? Maybe 6 or 10 turns at about 5 or 6 inches?

Been there - done that - even got the T-shirt with Maxwell's
equations on it. I suspect that your university never taught
the real thing.

> As it stands, all you can do is make one

I supported my statements with examples. Strangely enough, you
haven't posted any technical disagreement with my examples. All
you do is take potshots based on nothing except your feelings.

It's impossible to argue with you on a technical basis because you
have not posted anything technical. Do you disagree that the Z0
of a single #16 wire located 24 ft. above ground is ~600 ohms? Do
you disagree that such a wire can support standing waves whether
used as a transmission line or as an antenna?

Please post what you find technically wrong with my examples (all
based on valid distributed network reflection models) which I
learned in the 50's from "Field and Waves in Modern Radio" by Ramo
and Whinnery and a later edition of the same book in graduate school.

Hi John,

This term relates to the practice of "look alike" email,
correspondence and web pages that purport to be legitimate businesses.
One such example
http://web.ask.com/redir?bpg=http%3a%2f%2fweb.ask.com%2fweb%3fq%3dphishing%2bebay%26o%3d0%26page%3d1&q=phishing+ebay&u=http%3a%2f%2ftm.wc.ask.com%2fr%3ft%3dan%26s%3da%26uid%3d0CAE7F931C7039CF3%26sid%3d1403F394C318E9714%26qid%3dC7EDE92455EF9C46A616C9A2BDF01BE7%26io%3d0%26sv%3dza5cb0deb%26o%3d0%26ask%3dphishing%2bebay%26uip%3d1813385b%26en%3dte%26eo%3d-100%26pt%3dRecent%2bFraud%2bAlerts%2b-%2bFraudWatch%2bInternational%26ac%3d7%26qs%3d0%26pg%3d1%26ep%3d1%26te_par%3d108%26te_id%3d%26u%3dhttp%3a%2f%2fwww.fraudwatchinternational.com%2ffraud_alerts%2falerts.htm&s=a&bu=http%3a%2f%2fwww.fraudwatchinternational.com%2ffraud_alerts%2falerts.htm&qte=0&o=0&abs=...eBay+phishing+email+-+%26quot%3beBay+Reminder+%3a+Email+regarding+pre-indefinitely+suspended+from+eBay+%231%26quot%3b+August+04+2004...&tit=Recent+Fraud+Alerts+-+FraudWatch+International&bin=&cat=wp&purl=http%3a%2f%2ftm.wc.ask.com%2fi%2fb.html%3ft%3dan%26s%3da%26uid%3d0CAE7F931C7039CF3%26sid%3d1403F394C318E9714%26qid%3dC7EDE92455EF9C46A6
16C9A2BDF01BE7%26io%3d%26sv%3dza5cb0deb%26o%3d0%26ask%3dphishing%2bebay%26uip%3d1813385b%26en%3dbm%26eo%3d-100%26pt%3d%26ac%3d7%26qs%3d0%26pg%3d1%26u%3dhttp%3a%2f%2fmyjeeves.ask.com%2faction%2fsnip&Complete=1
(obtained by simply googling the terms "phishing ebay" and taking the
first hit that leads you to fraudwatchinternation.com).
There are literally DOZENs of fraud alerts for emails originating from
AOL (notorious for its simple access by simply opening an account from
one of any of 100 million CDROMS in the mail).

Anyway, the fraud proceeds by using lookalike names to the legitimate
commercial entity. Now, this lookalike is only slightly off from the
legitimate name such that you might be willing to follow the
directions from correspondence purporting to be from ebay.org or
ebaypurchasing.com or ebayaccounts.net or any of a number of variants
such as these. Another form of "spoofing" (giving the appearance of
legitimacy where the intent is to defraud) is to offer links to
legitimate commercial entities (often seen on the web page in the
traditional blue color) while the underlying html script points to
another address. In other words you click on what appears to be
ebay.com and you end up at 127.000.000.001 which is really the address
of a con artist. You cut a deal thinking you have been working with
ebay, and you have opened your account with Ossama.

This is all called "Phishing." The allusion is like it sounds, they
are fishing for your financial information to raid your bank and
credit.

Myself, I cannot think of going blind into any kind of correspondence
that starts out like this (a recent example from today):
>Here is Lucy Mcgraw. I write to you because we are accepting your mortgage application.
>Our office confirms you can get a $220.000 loï¿½n for a $252.00 per month payment.
>Approval process will take 1 minute, so please fill out the form on our website:
>
>http://hunter-crescent.net-cash.net
>
>Thank you.
>
>Best Regards Lucy Mcgraw
>First Account Manager

You should note that there are many red flags waving here. The odd
salutation; the misspelled word loan; the absurd low rate against the
principle, the promise of a quick application; and certainly a curious
signature that in NO WAY resembles the non-professional email account
name of xgrayqobeslegq@yahoo.com that originated the correspondence.
This lure screams Sucker Alert from end to end and is classic
phishing.

Click on the address and you can well expect to divulge something to
THEIR advantage in 1 minute!

Phishing. I trust this term is no longer lost on you.

Hi Dick

Excellent!

I use to chat to a fellow amateur many years ago that lived in a high
rise apartment. He set up his 144MHz yagi on a short tripod and pointed
it out the window. It was surprising how well it worked.

I didnt mention but another effective antenna for unit and condo
dwellers is aluminum foil antennas stuck to windows. This unfortunately
may not work too well for TV because of the need to keep directivity

Just for my interest what country/state/town etc are you in?

Cheers Bob VK2YQA

I think that you misunderstand what is being said.

Ham Radio is not a "hobby"; that is a description of
CB Radio.

Ham Radio is a technical pursuit for those suitably qualified - and
the M3/CB Fools' Licensee is not so qualified - he is specifically
forbidden to build his own gear from scratch and is therefore
not classifiable as a Ham by any stretch of the imagination.

You seem to be confusing a genuine concern that standards be
maintained with undesirable emotional attitudes that you yourself
project.

I append a short article to assist you to disambiguate the Ham from
the CBer.

------ooooo-----

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a

variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Dagnab it, Richard, double negatives or not, I appreciate the tutorial. Certain neurological events have reduced further my already modest ability and quickness in grasping, eg, phishing, sans elmering such as you provided. Otoh, it (the reduction) isn't all bad. I've recovered a portion of the longlost ability of looking at things with the eyes of a child, which eyes can overlook at least some of the egregious compartmentalization rife in adult discourse.

If nothing else, I get a kick out of your rhetorical flourishes, usually, once they sink in ;o)

Best regards's,

David Windisch, N3HE

Hi Mitchell,

Why do you need that many elements?

When higher gains are sought, other approaches are more effective, for a given form factor, than a Yagi-Uda.

What gain/beam do you need?

They use two antennas to implement spatial diversity. The system does a switched /RSSI when it gets a fade on the signal, on the hopes (usually pretty good) that the other antenna sees a peak rather than a null.

Hi Richard,

This READS like language, but doesn't really say anything, IMO.

Please ID the "techno-fraud" which you expose in your fractal antenna website--that's your word. And what patents do you claim your amateur web page has managed to render useless? You said this too.Hmmm:-)?

And what exactly is this early 1800's prior art you allude to that renders fractal antennas as public domain? Perhaps you have a knowledge base which extends before Hertz, and even Maxwell:-)?

I am sure I am not the only one who would share the fascination of details to your claims.

You are not a man short of words; use a few concise words to flesh it out, kindly.

73,
Chip N1IR

You could give it a try and see how it works for you, definitely
simple to do. Just because Cushcraft uses the 1/4 wave coax & radials
doesn't make that the 'only' solution. Another possibility is a
ferrite balun; type 43 ferrite torroids with an ID to provide a snug
fit over the coax. This approach is shown on some of the variation of
the J-pole so if you do a search for that antenna you may find a
starting point for the number/size of the torroids.

Makes perfect sense. The US and Russia have Sarsat/Cospas satellites
that monitor international distress frequencies (121.5, 234.0, 406
MHz) and alert regional search centers. This system can detect and
report much faster than random aircraft monitoring enroute. See
http://www.faa.gov/ATpubs/AIM/Chap6/aim0602.html.

I made a J-pole antenna for 10 meters a while back. Dont tthink there is any
reason you couldnt build a "copper Cactus" type of antenna that includes
these three bands.
There is plenty of info on this type of antenna on the net. I have not seen
any that include 10M though. Usually 6,2 and 432. Should be doable though.

Just because it is canceld in the far field does not mean the coil did not
radiate. I would not even say it is canceled in the far field although this
is a convenent way of looking at radiation. All you can really say for sure
is that the out of phase voltages in the receiving antenna combine
destructively.

I'm not going to waste my time arguing with you , Cecil; as you say,
been there, done that. I know there are people in the past who have
attempted to characterize antennas as transmission lines. It's an

old, hoary method. You have a copy of Balanis. He has references you can look up to see how close your ideas are to the truth.
Nope, I don't need to argue. I have a wife who is always willing and ready to provide arguing services whenever I need them. I don't need you.

Hi Richard,

Indeed. And Kraus' speculation in this
regard has been the basis for some
debate, if I recall.

It is my opinion that .1 lambda spacing
has been somewhat established as
optimum spacing for a 2 el yagi with a
director - and I get the impression that
this is the basic structure that Art is
using as a benchmark.

Perhaps the next step is to determine
whether the modeled gain Art is getting
is a result of artifacts or not.

It is generally accepted that if RF energy doesn't escape to the far-field, that energy is not "radiated". Energy can appear in the near-field around a wire without being "radiated".

> I would not even say it is canceled in the far field although this
> is a convenent way of looking at radiation. All you can really say for sure
> is that the out of phase voltages in the receiving antenna combine
> destructively.

If the fields combine destructively in the near-field, that field energy is returned to the system and never reaches the receiving antenna in the far field. That's how transmission lines are supposed to work and why the spacing between the two conductors needs to be negligible compared to a wavelength.

The near-balanced currents on each side of a coil, traveling in opposite directions, cause destructive interference in the near field, thus limiting the amount of energy radiated by the coil. An electrical 1/4WL helical antenna radiates slightly less RF than does a 1/4WL straight wire. That implies the amount of radiation from an air-core coil is slightly less than from a wire the same overall length as the coil.

Unless somebody knows better, the most common sequence would be highest
frequency first, lowest frequency last. I presume you have this mounted on a
car. Make sure you have a good ground connection.

If it actually radiates and if that radiation destructively combines
at one receiving antenna, then radiation must constructively combine
at another (potential) receiving antenna, or else the conservation of
energy principle would be violated. Any far-field destructive interference
event must be exactly balanced by an equal magnitude constructive
interference event at some other location in the far-field. If there is
a receiving antenna there, it will experience gain over the first location.

And a coiled up antenna is likely to experience a lot of I^2*R losses.

Hi Art,

To be honest, I suspect you will not
find much data IRT to what you are
doing here. However, I suggest
making some effort to determine if the
extra gain you are seeing in the
models are a result of artifacts or not,
would be helpful.

If you haven't already done do, I would
be trying frequency sweeps over a
limited bandwidth, and scaling them to
higher frequencies to see if the results
remain consistent. If not, this could be
an indication of artifacts.

I get the impression you are making
physical models to test as well.

Perhaps scaling to a much higher freq,
say 50 or 145 mHz or so, would make
FS tests more manageable.

The goal, is to simply determine if the
gain of the experimental structure is
greater than that of the benchmark
(the 2 el yagi) - measuring the exact
amount, should be of no real concern
at this point.

Don't want to argue, Tom. I just want you to make a posting that
contains some iota of technical content. My ten-year-old grand-neice
could easily have thought up your last dozen (mostly ad-hominem) postings.

> I know there are people in the past who have
> attempted to characterize antennas as transmission lines. It's an
> old, hoary method. You have a copy of Balanis. He has references you
> can look up to see how close your ideas are to the truth.

Since you brought up Balanis, here are some quotes from Chapter 10 of
his book that should impress you:

"The sinusoidal current distribution of long open-ended linear antennas
is a standing wave constructed by two waves of equal amplitude and 180
deg phase difference at the open-end TRAVELING IN OPPOSITE DIRECTIONS
along its length" page 488 (emphasis mine)

"THE CURRENT AND VOLTAGE DISTRIBUTIONS ON OPEN-ENDED WIRE ANTENNAS ARE
SIMILAR TO THE STANDING WAVE PATTERNS ON OPEN-ENDED TRANSMISSION LINES."
Page 488 (emphasis mine)

"Standing wave antennas, such as the dipole, can be analyzed as traveling
wave antennas with waves propagating in opposite directions (forward and
backward) and represented by traveling wave currents If and Ib." page 489

Uhhhhh Tom, following Balanis' direction is EXACTLY what I have been doing.
Since you disagree with Balanis, it appears that you have never cracked
open his book. I, OTOH, have attended Balanis' antenna classes at ASU
and worked hand in hand with him on a joint Intel-ASU project.

Somewhere around here, I have the details on a mobile antenna that is
about one foot high. It was mounted on top of a van and had a top hat
that hovered one foot above the top of the van and was exactly as big
as the top of the van. It is supposed to be one of the most efficient
mobile antenna radiators of all time.

Also, consider that those radials arn't there just to decouple the coax!
they are also there to form a 1/4 wave ground radial, 1/2 wave down the pipe
to form a counterpoise for the Ringo- Something that the toroid would NOT do,
if memory serves me correctly!

>
Chuck, I am an experimentor, I am not advocating changing the aproach to
antennas by amateurs
When light weight fishing poles on E Bay became less than a dollar a foot
I was able to get rid of most of my aluminum stock.When I got Beasely's
NEC Pro program all prior constraints regarding antenna experimenting
were removed (ala aluminum or copper foil). Last year I made a 160M dipole
that was rotatable
and frequency controlable with moveable bandwidth, I succeeded, but it still

was a large structure
and winter provided many unwanted occasions to repair the unexpected. This winter I am being
less ambitious and am confining myself to a 8 foot boom. First I was to check if more elements
can improve the gain. From prior experiments I knew that feed impedance can be change upwards
by placing an element close the rear of the feed dipole which is contrary to the ARRL handbook.
I also was aware from previous experiments that element diameter was very important if one is
not controlled by mechanical requirements. I also knew from reading that in stacking when
only the bottom array was being used one obtained protection from static noise so this would
also be a good opportunity to have one element say 30 inches higher than the rest on the mast
which would be part of the original array to give room for experimentation.
My present model has a gain of 13 dbi at a ht of 820 inches over perfect ground and is less than 2:1
across the audio portion of 20 M. The number of elements is six which suggest things are heavy but with
fishing poles it is extremely light. ( note, fishing poles when ice laden bend as if it had caught a fish and
the ice then slides off) I have not used the f/b to rest upon as I believe that the lower lobe at the rear is not
important where the second lobe is when considering direction of propagation.
So thats it Chuck, I enjoy myself with playing with antennas to find out things for myself as I have
more options at hand that the ARRL have not considered as yet and thus are not held hostage
to the knoweledge of the many psuedo experts who thou knoweledgable about the past which is very
usefull have decided that there is no future since all is known. By the way with the advent of cheap cameras
< $30 it is easy to place a SWR meter or power meter right at the feed point and eliminate questions regarding
transmission lines.
Regards
Art

The malfunctioning TV was reportedly 'transmitting' on 121.5 MHz. Detecting 121.5 MHz by satellite is done from Low Earth Orbit (LEO) and depends upon waiting for a satellite pass (typically several hours - not instantaneously). I would have thought that there was more air traffic (airplanes) over Oregon than that - most places have lots of airplanes passing overhead nearly constantly.

Perhaps it was his exact location and blockage by mountains. Maybe the timing was coincidental. OK then...

Looks like Tom would rather argue with his wife than with Balanis or me.
(I don't blame him for that.) I had relatively long discussions with Balanis
and he personally agreed with everything I have posted although he didn't
go to such lengths in his book.

Who's going to publish it? I spent a lot of time preparing an article on
what happens at a match point and QEX refused to consider publishing
anything that disagreed in the slightest with Dr. Best who denied there
is such a thing as interference at a match point. (Hint: Without interference,
a match is impossible in a system with reflections.) There's a good-old-boys
network in amateur radio. If you are politically incorrect within the ARRL
political power structure, you are black-balled from publishing. It doesn't
matter if you are technically correct. The current through a loading coil
is constant by definition in that good-old-boys network. Forget reality.

100% QSL
we can give it a try, there is always internet and e-Books.
It is amusing to see two versions of current in loading coil in ARRL published books, one version in Antenna Book, Compendia and Handbook vs. other in ON4UN Low Band DXing.

For many years, we kept a good deal of practical info on fractal antennas on that web site. However, after Summer 2001, as a prudent but voluntary precaution, we have consistently vetted inquiries and prevented unbridled dissemination. That this also apparently confuses the competition is an added bonus.

Unfortunately, hams--as hams-- no longer have access to that info.

If you saw my e-mail, you would be less puzzled.

Be sure you specify "Penetrox - A" which is for Aluminum. At one time, there were a half-dozen versions for different
applications, each with a different formulation. Some of the others contain Nickel, which is a no - no for RF, at least
if you want low intermod performance.

OK...I read the above...I also received the email....to put what you're saying into simple terms is that there are no commercial (non-proprietary) fractal antennas available on the commercial market. Thus, no "commercially available" fractal antennas. QED.

Andrew, this is amusing but rather silly.

Public domain does not go with "commercial" unless you are a Linux guy:-)

There are plenty of commercial fractal antennas available. Which one? Depends on the app.

You know how to pursue them. I told you how to proceed. I will not use this NG to sell you anything, my friend.

Have a pleasant weekend; we've exhausted our discussion on this forum.

>Jim NN7K

Hadn't fully looked at that aspect as this antenna is billed as a 1/2
wave not requiring a ground plane. Your memory does serve you
correctly though; the toroids, or a choke balun, would not perform
that function. Those I know who've used this antenna fall in two
camps, with no middle ground, some swear by it and others say it's a
nice antenna to use to mount their 1/4 wave verticals. Can't say from
direct experience though as I've never used one. For verticals I've
only used 1/4 and 5/8 wave antenna's and those have been home brewed
so easily I couldn't bring myself to pay for one.

Thanks for the added perspective Jim,
Howard KE6MAK

Howard- one other perspective-- ' twas at ARRL convention , Many moons
ago, in Seattle (home of AEA , at that time)- They were selling their "NEW"
Isopole sntenna" . One of their bigger selling points was " NO extra radiation
from their antenna And, with a loop, and a # 43 lamp, demonstrated, side by
side with the Ringo Ranger --, and the lamp lite brightly, next to feedline, and
the MAST of it, while NO Light was exhibited from the feed, or mast of the Isopole.
This showed that there was no "Wasted power", Wrongful radiation from the coax
or mast to screw up the antenna pattern, and it was only a short time thereafter
that Cushcraft introduced the model II, with the ground radial on present day
versions! That was their answer to the problem of getting a consistant pattern
from these antennas! NN7K

Correction: Two versions in the ARRL Antenna Book. The first illustration,
Fig 7 on 16-4 in my 15th edition shows the current taper across the coil.
Fig 10 on 16-6 shows no current taper across the coil. :-)

Actually the Russian COSPAS satellites have long since gone out of
operation and Russia has no plans to launch any future birds in this series.
The reported incident concerning the plasma TV transmitting a signal on
121.5 is one of the reasons that this frequency is being discontinued as
a primary frequency. Current regulations dictate the use of emergency
transmitters on a general frequency of 406 mhz. There are more than one
channel in use due to the large and growing number of ELT/EPIRB/PDR
units out there. For ground search the 406 units include a 121.5 low
power transmitter.
A properly registered and equipped 406 radio can reduce the search area
from a 20 mile radius to less than 5 miles. GPS augmentation can lead to
a radius of 15 meters or less.
I can't tell you how many false ELT tracks I have worked on as a Ground
Team Leader for the Civil Air Patrol but I did work on an actual track
as Incident Commander that resulted in the location of a double fatal
air crash. Aircraft and satellites reported the elt signal and my ground
team, guided in by aircraft, walked right up to the crash. In fact the

df operator tripped over the engine.
As to why the satellite picked up the elt and not an aircraft. The satellite is designed to pickup the elt and all the aircraft is doing is listening to 121.5. The commercial pilots have and do pick up a lot of elt signals. Usually the satellite has also picked up the same elt sometimes not.
Radio signals are funny things Sometimes you can walk right up to the transmitter, sometimes you have to work for it.

I encourage you to look into the Civil Air Patrol. We are the official USAF Aux. A full member in Homeland Security since before Homeland Security was popular.
Look up web page: www.cap.gov for information about CAP.

Or what about his abuse of the repeater system for which he was
spanked by the rain report?

N8WWM guilty of FCC violations. According to the FCC, N8WWM, Dog
Adair committed several violations over the air at the expense of the
Toledo Amateur Radio Club by utilizing their repeater to break the
law. The amateur club received a warning letter from the FCC
concerning Adair's violations and were told to take steps to make
certain the violations by Adair will not be repeated. Adair not only
hurt the entire image of amateur radio with his inexcusable behavior,
but damaged the reputation of yet another entity trying to further
the good of amateur radio. It's a shame when bad apples like these
make it so clubs can't even trust their own users to abide by the
rules they were sworn to uphold. Adair is also an infamous presence
on the internet. A google search of "N8WWM" reveals a peek into the
world of the individual identified as Adair. In addition to FCC
violations, Adair has, in the past, been accused of being a prolific
spammer, breaking several internet laws and violating several terms
of service agreements with internet providers.

# 1209. How reject QRM from the fence ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-24 11:30:05 UTC
From: Thierry <->
Message-ID: <417b924a$1@news.vo.lu>
Source record: 87704

Hi,

I friend of mine, ham, is handicapped and cannot move without his wheelchair
He experiments QRM on low bands 160/80/75m induced by the fence installed by
his neighbor
I don't know what kind of fence it is, and if it is really close to his
house or miles away...

He would like to know if a rotaty loop antenna could remove this QRM ?

I used a Wellbrooks ALA1530 and I am not sure that he could remove such QRM
as it.

Usually a fence has HV pulses generated by a large ignition coil or similar
transformer or this is maybe a thermostatic device

I see three solutions:
- I 'd like to know if there is a way to install on the fence itself a
"de-parasiter", something like a low-pass filter that 'd cut all trancient
emissions in HF bands ?
- or could the MFJ noise canceller (MFJ 1025/1026) be a solution (tightening
a second antenna like a long wire 20m long outdoor)
- at last is there another model of receive antenna that could really reject
this kind of QRM ?

Any other idea or an URL ?

Thanks in advance

Thierry, ON4SKY

Hello Thierry ON4SKY or LX2SKY,

I worry there is few things to do with this kind of electric fence because the sharp pulses are inherent to the system of protection. And certainly a directional antenna can help in reducing or even cancel the QRM depending on the proximity (you didn't mention the frequency bands listen by your friend).

On the other hand there are in Belgium (or in Luxembourg) regulations about interferences. Nobody is allowed to pollute the frequency bands. If this problem remains after discovering the owner of the fence and you can't find an agreement with him, you have the possibility to call the IBPT at the following address:

"Toute personne peut s'adresser au NCS pour signaler des perturbations de
nature radio�lectrique.
Le NCS peut �tre contact� par courrier, par t�l�phone ou par e-mail �

Source record: 87709

Thierry:

Two answers:

The interference is pulse in nature, and a "noise blanker" of the type which was effective against the "Woodpecker" HF
Radar is effective.

In the States, there are fence chargers which emit no RFI. Their charging pulses are shaped to prevent it.
Unfortunately, it has been 10 years since I have dealt with that problem, and I no longer recall any brand names or
model numbers.

And, Jacques is correct, that interference is against radio regulations, and there are legal recourses which can be
pursued if all else fails.

>on the app.

Which gets back to the original question. WHO? Your site seems to be the only one, and all seems to be "proprietary" (by your own admission). So, "limited proprietary designs" would be a better term to use than "commercially available," which implies a broad (i.e. commercial) market. Silly to claim "commercial" when no one is offering them except in proprietary designs. 'Nuff said.

Tom Donaly wrote:
> For those who really want to
> know the truth, go to Tom Rauch's web site and read about loading coils.
> (He doesn't use the term "current drop" once."

I'm glad you used "truth" instead of "facts". Tom's truth doesn't
agree with scientific fact. You guys have turned your "truth"
into a religion.

Is there a current drop in a transmission line from the current
maximum (loop) to the current minimum (node) when standing waves
are present?

Is there a current drop from the feedpoint of a helical 1/4WL
antenna to the tip of the antenna?

If a coil occupies 90 degrees of a standing-wave antenna or an
unterminated transmission line with reflections, the current
can be maximum at one end of the coil and zero at the other.
The electrical 3/4WL antenna below consists of 1/4WL of wire,
loading coil, and 1/4WL of wire. The net current at one end
of the coil could be one amp while the net current at the
other end of the coil is zero. If you don't understand that
fact, I feel sorry for you.

coil
Feedpoint---1/4WL wire---x-///////-y---1/4WL wire---

When the above antenna is made resonant, the net current at
'x' is zero while the net current at 'y' is maximum. How do
you explain a coil with zero current at the bottom and one
amp at the top? It happens all the time in distributed
networks.

If a coil occupies 180 degrees of a standing wave antenna or an
unterminated transmission line with reflections, the current
can be zero at both ends and maximum in the middle. Such a
configuration is illustrated in "Antennas for all Applications",
by Kraus and Marhefka on page 824.
--
73, Cecil http://www.qsl.net/w5dxp

"The current and voltage distributions on open-ended wire antennas are
similar to the standing wave patterns on open-ended transmission lines ...
Standing wave antennas, such as the dipole, can be analyzed as traveling
wave antennas with waves propagating in opposite directions (forward and
backward) and represented by traveling wave currents If and Ib ..."

Over here, commercial means you sell to businesses and/or consumers in a profit oriented enterprise .

If you mean 'consumer off the shelf', no; don't do that.

The mission is to help define your needs and deliver solutions. Solution could mean: services; vended product; licensed design, most likely in reverse of that order.

# 1225. Gas lines and ground rods

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-24 17:10:04 UTC
From: wntu4@yahoo.com
Message-ID: <6c7a372f.0410240910.49193ca1@posting.google.com>
Source record: 87720

Hi all,
Am designing my shack, and I think I have a problem.Very near the shack entrance is the entrance of my natural gas line to the house, plus meter. Now I know I cant attach ground to gas line.... the question is, how close can I get my rods? I plan to use 3, one right outside the entrance, and the others 10 feet to either side. I dont have the option of running away from the house more than 3-4 feet. The first rod would be about 3-4 ft away from the gas line, but the ground strap will have to go very very near the gas line. Am I looking at an explosion in the event of a lightning strike? or will a few inches of earth be enough insulation? I should point out that there appears to be an aluminum ground rod driven into the ground at the same point the gas line exits the earth. Thanks for any advice and information!

My Webster's has 74 definitions of "drop" including: "a decline in amount" and "diminished or lessened". The current at a current node has certainly declined from the current loop and is certainly diminished from the current at a current loop. The only definition of "drop" in the IEEE Dictionary is "A connection made between a through transmission circuit and a local terminal unit". The IEEE Dictionary doesn't define "current drop". Neither do any of my technical reference books.

So Tom, please provide a definition and a reference for your version of "current drop". I suspect you are as wrong about the definition of "current drop" as you were about the contents of Balanis' book.

## 1228. An easy experiment with a coil

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-24 18:09:33 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <417bedfe_4@127.0.0.1>
Source record: 87623

The results of the measurement of current at the bottom and top of the coil
in an off-center-fed dipole configuration should leave no room for doubt.

------1/4WL------FP------1/4WL------

Start out with a 1/2WL dipole. Measure the resonant fundamental frequency.

Then, to one end, add a coil and another 1/4WL of wire

------1/4WL------FP------1/4WL------//////------1/4WL------

Adjust the coil inductance so the antenna is resonant on three times
the fundamental frequency of the original dipole.

Measure the current at the left(bottom) of the coil and measure the
current at the right(top) of the coil.

The current at the left of the coil will be nearly zero. The current
at the right of the coil will be approximately the same as the feedpoint
current, somewhere around 1-2 amps for 100w input. This can probably be
demonstrated using the helix feature of EZNEC.

A 2:1 VSWR bandwidth over the 20m
phone portion implies a good Q, but
aren't you even a bit curious if the gain is
indeed as high as 13 dBi?

I seem to recall from years ago, a yagi
that had several close spaced directors on
a relatively short boom - I just can't recall if
it was commercial, in an article, or any
other significant details about it.

The camera idea is a good one :)

There are always new things to learn...

My latest experiments have produced some unusual antennas:

A unique dipole that does not inductively couple with surrounding conductors (the perfect attic dipole), that can be 'tuned' at ground level, which, at first glance, appears to have a somewhat omni-directional pattern.

A reduced-noise (E-field loaded) vertical for 40m with a VSWR bandwidth of 1.3:1 from 7.0 to 7.3 mHz, (it's not a dummy load as one would generally deduce from the above description), and has proven to be as good a performer on DX and local as my conventional top loaded vertical.

The conventional vertical sees a noise level here of around S-7 or greater, and the E-field loaded vertical, around S-3 to S-5 (on IC-756, normal BW, no NB, no DSP).

Neither of these were developed using computer modeling, though.

Keep up the fun...

73 de Chuck, WA7RAI

That's pretty cruel, Richard, not allowing even the village idiot
to ask for a reference. How anyone can argue that there is no current
drop between the current antinode (maximum) and the current node
(minimum) is beyond belief. No drop from maximum to minimum is a
concept that would obselete all of human knowledge.

>house or miles away...

Hi Thierry,

First, find the offender. This is easy because, as you have experienced, the noise is everywhere. With that in mind, hop in the car and tune it in. Drive around and make it louder. You will then have answered the question as to where it is located.

Second, the reason why it is loud, much less louder. Electric fences fail for one of several reasons. Poor ground (how about that?) can offer problems, but it ranks pretty low. Poor connections can frustrate, but they are simple to fix if you simply walk the fence and inspect. Arcing can occur, but this is often confined to the lowest wire that is being brushed by grass, which then burns off with a sizzle (across the spectrum). Trimming vegetation takes care of that (and has you walking the fence line once again).

A useful tool to take along is a circuit tester with a neon bulb. It should light up at the right places (or the wrong places) or dim in the wrong places (or the right places). Again, this has you walking the fence line.

Expect to visually inspect along the fence line.

I am putting up folded dipoles, one for each band I want to use. So far I have 3 and I need to think about a switch .

I want to run all these ladder lines to a switchbox outside my cabin and then run one coax thru the wall.

The ARRL handbooks have had suggestions for antenna switches but they were all for coax. Has anybody built this for ladder line, and what would be different?

First what do I connect the ladder line to, something like a set of banana plugs would work, but could those plugs be in a metal housing, how would the proximity of the metal affect the ladder line?? And the switching??
Would a double throw relay work??

So many questions...

Thanks for any answers

Uwe

I am providing you some comments, and excepts, but your personnel safety in these matters dictates that you obtain professional assistance, which I am NOT.

1, Gas piping may NOT be the *primary* grounding electrode conductor.
2. Gas piping is REQUIRED to be bonded.

The ground electrodes you refer to installing outside your shack, these are presumed to be the closest electrode connections for your station single point ground? If so they must NOT be the same ground rod that will perform the requirement of (minimum of two) lightning downconductors per structure, or the grounding earth electrodes for those downconductors. But the station single point ground MUST bond to the lighting protection system (AFTER) the lighting downconductors have FIRST terminated at their OWN grounding electrode or system thereof. The station single point ground must ALSO bond to the home electrical service entry ground. You *should* discover your gas piping is already bonded to the service entry ground in accordance with code. But parts of the NEC and NFGC relating to this bond are fairly recent. I strongly recommend you hire a licensed electrician who demonstrates experience with lightning protection systems. If you come up dry on this search after several telephone calls, start calling professional (electrical) engineers who specify lightning protection systems. Call other areas if you come up dry there.

A few excerpts related to your query:

Equipotential bonding of all metallic supply lines entering a building is a vital requirement for protection of a building and its contents. Gas piping systems are specifically required to be bonded to a grounding electrode in accordance with the National Fuel Gas Code NFPA 54/ANSI Z223 and the National Electrical Code ANSI/NFPA 70. The grounding electrode is a

requirement of the National Electrical Code.

The 1999 and 2002 editions of the National Fuel Gas Code require that "each above ground portion of a gas piping system upstream from the equipment shutoff valve shall be electrically continuous and bonded to any grounding electrode, as defined by the National Electrical Code, ANSI/NFPA 70." Bonding jumper shall be sized in accordance with NEC Table 250.66.

An equipotential bonding connection shall be made between the fuel gas piping system and the electrical service grounding electrode. The bonding jumper should be sized in accordance with NEC Table 250.66 (based upon the rating of the largest overcurrent device protecting the feeder that supplies the building - typically 200 amps). Bonding and grounding connections are to be made by a qualified technician.

Hope this helps,

Jack Painter

Message-ID: <qIVed.33157$5v2.16027@fe2.columbus.rr.com>
Source record: 87641

I am installing a G5RV antenna, and a new ground for my TS-2000. The radio is in the center of the house, and instead of running a long ground wire to a ground rod at the outside of the house, i was thinking of drilling a hole directly below the radio room in the basement floor and driving the ground rod there. That would make the ground wire only 6-8' long. Assuming i do not find a wastepipe while driving my ground, is there any issues with getting a HF ground this way?

Also, I was going to install lightning arrestors at the radio and ground them to the new ground rod, is it better to place the lightning arrestors and an additional ground rod where the coax enters the house, or will this cause ground loop issues?

Thanks in advance to the collective wisdom of group.

Hi Gerry, You are dealing with two different grounding issues, and I can't comment on the ground loop one. The purpose of the lightning protection ground is to make sure that most of the current from a strike gets to ground the way you want. And you want it NOT to go thru your TS on its way to ground.
A ground directly at the rig can be a safety ground as well as an RF ground. What you describe sounds like you are trying for an RF ground at the rig and a safety ground at the entrance to the house. You may not need an RF ground, I would concentrate on the safety aspect, and add the RF later if needed.

Gerry, if the G5RV is a non-radial using antenna (function is complete, as in a dipole), then this so called RF ground from your transmitter will be of little if any use. If you ran ladder line to it directly from the transmitter or tuner (and you were willing to tolerate RF in your shack and your home) maybe you do need an RF ground! <G> Assuming that's not the case, and you just want an RF ground anyway, the shortest path via minimum 3" wide copper strap would provide a good one, regardless of its basement location

Here is where you are mixing apples and oranges, because ground loops and lightning protection are not related. The only time lightning arrestors should ever be inside the shack is when they are immediately attached to the station single point ground *when that is inside the shack*. Mine is for instance, but I am also alongside an outside wall under which is the entry-point for all coax, and the shield-grounding point for same. If you are transmitting from an interior room, far from the coax entry point to the home, then the coax shields should be grounded outside the home and lightning arrestors installed there. The key is to have the lightning arrestors on as short a connection to real earth ground as possible. Preferably within 1' but in no cases more than 4' (via extremely low impedance and high current capability connectors) from earth ground.

Your location indicates that an outside bulkhead (some call this a "ground window") might be ideal. This would typically involve a copper plate attached to the external coax entry point of the home. Bond this bulkhead

immediately to a minimum 5/8" x 8' ground rod (and bury the ground rod top, do not let it protrude above ground). Ground all coaxial cable shielding to the ground rod (or *heavy* strap leading to it) and attach the lightning arrestors directly to the copper bulkhead above that. Then add a second and third ground rod, each fanning out from the first and a minimum of 12' from the first (16' is recommended).

If you are able to, install a very heavy (#2 or #4 copper) bonding conductor from your inside station ground (this might be in your basement) to your electrical service entry ground. Also bond the AC service entry ground rod to your outside coax entry grounding bulkhead. *If* you are able to accomplish that, *and* you have good surge protection installed at 1: the AC service panel, and 2. the point-of-use in your shack, then it would be safe to leave the transmitter plugged into AC during a storm. Otherwise, no matter how good your external grounding bulkhead and attached lightning arrestors, there will still be a path for enough damaging potential from ground to your radio, and out through the AC power cable. The critical bonding conductor from radio to AC service entry helps but cannot eliminate this path. Without it, there is no safe connection to AC power during a storm, no matter how good the surge protection is.

Jack and others,

Thanks for the weblink, this helped me understand what is going on with grounding.

will go for external lightning grounds at feedlines, and extend the AC safety ground to the shack. will give this a try !

You could use a few high current (30A) relays. Double pole double throw types. If you nest (aka: boolean triangle) three of them, you could easily switch four antennae into one common buss.

Something like the NTE 30amp unit (nicely spaced contacts, and lots of space between poles.)

If you get ones with 12 or 24 volt DC coils, you can control the whole matrix with common 3 pair 24AWG phone wire. (you could even get away with 2 pair if you set them up with common ground)

Good luck and don't forget to use a few toroids on the DC feeds to the coils!

The MFJ-1796 covers 2, 6, and 10 (and 15, 20, and 40m).

## 1256. Re: Ladderline switch

Well, "it depends". Wide spaced, open frame, ceramic base relays are ideal for switching ladder line. A knief switch is a good manual alternative. Best of luck...

> The conventional vertical sees a noise
> level here of around S-7 or greater, and
> the E-field loaded vertical, around S-3 to
> S-5 (on IC-756, normal BW, no NB, no
> DSP).

I'd be very leary...Also would depend on the polarization of the
noise, and any possible changes in the pattern...But in general, if a
certain vertical picks up more far field noise than another, it's the
superior vertical. Noise is rf like any other signal. So unless I'm
missing something here, the conventional antenna should also receive
the *desired* signal better than the low noise version. And being
things are generally reciprical, it should probably transmit a better
signal also...How careful have your on the air tests been? Are you
quickly A/B'ing using a switch?
Needless to say, I'm kind of dubious of the claims of equal
performance. Unless the noise was common mode or polarity related,
I've never seen an antenna that received lower noise, outdo one that
picked up more noise. If the change is not efficiency related, that
would leave me to think that your vertical pattern is being skewed
somewhat, and is more horizontally polarized than the other, and thus
, picks up less vertically polarized noise. If thats not the case, I
would think the low noise version is less efficient. Just my opinion
tho...

I can't believe that the measurements are that critical.

Denis can always start with 30 cm, and then trim - if required easier than lengthening the radial ! :-)

Message-ID: <rLKdncMyOMqq9uHcRVn-pw@adelphia.com>
Source record: 87655

Hey Butternut owners!

I bought a HF6V at a hamfes recently. It's installed now, and I am in the process of tuning it this weekend.

80 and 40 are okay soo far. 20 meters is a different story. One of the things I found out was that there was an extra HV cap. Apparently this goes on the 30 meter coil/capacitor assy. But the assy was disassy!

Does this cap go in series with the coil at the top, or does it go in parallel as do the 80 and 40 meter caps?

TIA - Mike KB3EIA -

Funnily today I changed the model slightly
and the gain exceeded 14 dbi with an increase in Q
So this is the model that I am going to make but
with the anticipation that by curving the elements
I will narrow the beam width. It shows 66 degrees
at the moment and a take off angle of 12 degrees.
It should be up in a few weeks. When I test I will look for
feed impedance and lobe width using a laptop program
with a distant signal.

>

> other significant details about it.

It may have been the 13 element I made for 20 M
on I think a 80 foot boom and that was the first time I used
two reflectors to get a 50 ohm feed.
I seem to remember that Roy modelled that also on EZNEC
or is it ELNEC and he confirmed the 50 ohm feed as did
my modelling and the actual antenna.This was about 10 years ago.

I forget where I saw it (maybe in the MFJ catalog) - but I've seen a device
used for cancelling unwanted signals.
I think the principle is that the second (smaller) antenna should pick up

the unwanted signal -and have an attenuator on it - it adds to the original signal, but in opposite phase so as to cancel.
Used mainly to block locally strong signals so you can hear remote weaker signals.
The second antenna - being smaller - only picks up the strong local signal.

A hole through the floor is not always a good idea, especially if the place where you drill is near the center of the foundation. The soil underneath is probably very dry and of no value for any sort of ground.

Jimmie wrote:
"I would not even say it is canceled in the far field although this is a convenient way of looking at radiation."

Kraus writes on page 23 of his 1950 "Antennas":
"Directivity=maximum radiation/average radiation.

The radiation is in watts per sq. mtr.

The famous round balloon example applies. The balloon is filled with so much air (an analog for the radiated energy). Squeeze the balloon. Energy like air, increases in the directions it isn`t squeezed in, but the total amount of air is unchanged and like the balloon air, the radiated energy total is a constant in the analog.

The idea that energy still exists where suppressed by interference is illogical.

Best regards, Richard Harrison, KB5WZI

Hi Irv,

One might thinks so (dry), but this is the second hill I've lived on
the top of. The first one had a neighbor who had an underground
spring running through his basement. Here, I have two sump pumps with
a perimeter drain for the same reason.

Same material as has been offered for 6 to 8 years at:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
which includes 143 pages of other data.

>
>http://www.itm.mh.se/forskning/elektronik/Posters-2002/posters/PosterFractalAntennas.pdf
duplicate link but as it also covers variations over iterations, same
material as has been offered for 6 to 8 years at:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Band%20Comparisons.htm
which includes another 17 pages of data; or
http://www.qsl.net/kb7qhc/antenna/fractal/Wide%20Band%20Comparisons.htm
offer another 8 pages (6 related to the specific example offered by
Bill)

However, the Triadic Koch is hardly an exemplar of the field of
fractals. The Quadratic Koch usually exhibits better characteristics
(clearly seen in the data from the pages offered).

There is nothing remarkable in the particular form, and even less in
it having a "respectable" name. In fact, the "field" (which is the
equivalent of academic mongoloidism) is so inbred, that you see the
same Kochs breathlessly trotted out every 6 months as though a new
breakthrough has been achieved. I don't blame them, they don't read
each other's papers anyway, and each researcher trusts theirs is the
first groundbreaking discovery. Generally they focus on metaphysical
formulas (you can find my own if this is your reading preference) with
the unstated premise that there is some causal relationship between
form and function. There is, but these gowned clowns haven't got a
clue.

Such antennas have simple rules if you wish to achieve both gain and
matching characteristics, and it has nothing to do with the eye-candy
visual appeal of snowflake forms.

Such cute antennas may sell to the rubes, but you can wave PhDs at the suckers to the same effect and they will throw loose change at you. The marketing is similar to the traveling carnival's freak shows. Some call this success in the marketplace and are rightly ashamed to display their product. ;-) After all, once your audience has seen the novelty, discovered how banal it is with casual exposure, the trade evaporates. The Carny experience lies in playing to the fetishes of mystery and the purchased exclusivity with shared secrets of a deformed world. Psychologists call this thrill "Voyeurism."

# 1270. The "TRICK" to TV 'type' Coax Cable [Shielded] SWL Loop Antennas {RHF}

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-25 09:12:55 UTC
From: rhf-newsgroups@pacbell.net
Message-ID: <ff3145e8.0410250112.24a2abe3@posting.google.com>
Source record: 87665
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.antenna

YODAR,

The "TRICK" to TV 'type' Coax Cable [Shielded] SWL Loop Antennas {RHF}
http://groups.yahoo.com/group/Shortwave-SWL-Antenna/message/1626

I too tried to build a Coax Cable [Shielded] Loop Antenna
that was made of "TV type Coax" that had a 'Shield' made
of Foil and about 33% Braid. The Results were very poor.

Then I Got An IDEA "*" ! { K I S S }

Why not use "Pre-Made" Parts :o) WHAT ?

* One Piece of TV type Coax Cable with the "F" Connectors
on both Ends. This can should be these Pre-Made Lengths
Three Feet (3 Ft); Six Feet (6 Ft); Nine Feet (9 Ft);
Twelve Feet (12 Ft); and Fifteen Feet (15 Ft); ETC.

* One "F" Connector to PL-259 Plug (SO-239 Adapter)
RadioShack Catalog # 278-258

* One TV type Two-to-One Splitter with "F" Connectors.
Get the one with the two Output "F" Connectors on
'opposite' Sides and the Input "F" Connector on the
Bottom (looks like a 'T').

THE SECRET IS TO BUILD A <NEXUS> LOOP-HUB:
Using the Two-to-One Splitter. Remove the 'Seal' Plate
from the Body of the Splitter. Remove the Ferrite Core
and Wires from inside the Splitter. Next clean a 'Spot'
inside the Body of the Splitter for a Solder Ground-Point.
Use a Solder Gun (150W) to make this Solder Ground-Point;
get in and get out quickly so that you do not melt the
plastic insulation inside the "F" Connectors. Wrap a
Wire around the Left "F" Connector Terminal. Route this
Wire to the Solder Ground-Point on the Body of the Splitter.
Using a Soldering Iron (35W) and Solder the Left Terminal
and the Ground-Point. Next 'wrap' a Wire around the
Bottom "F" Connector Terminal; and 'route' the Wire to
the Right "F" Connector Terminal. Then you need to make
a 'new' "Metal Cover" for the Splitter. I used one of
those old AOL CD "Tins" that come in the Mail. They are
thin enough to 'cut' with a Heavy Pair of Scissors .
Cut and Trim a piece until it "Fits". Ensure your have
good Metal-to-Metal 'contact' between the Cover and
the Spliter and Glue them together for Security. You

now have the <NEXUS> "LOOP-HUB" of your Coax Cable Loop Antenna.

The Three Feet (3 Ft) piece of Coax Cable is your Feed-in-Line.

MAKING YOUR "INTERCHANGABLE" LOOP ANTENNA ELEMENTS:
The Six Feet (6 Ft); Nine Feet (9 Ft); Twelve Feet (12 Ft) and Fifteen Feet (15 Ft) Coax Cable are your [Shielded] Loop Antenna Elements. Fold them End-to-End and 'mark' a One Inch (1") Area at the Fold as their Mid-Point. Very Carefully 'cut' the Outer Insulation and then the Foil and Wire Braid away and out from this One Inch Area. {Do Not Damage the Inner Insulation and Center Wire of the Coax Cable.) Tape this One Inch Area and an Inch on each side for Strength and Security.

TIP: If you have a Plastic Hula-Hoop or some 5/8" or 3/4" (White) Low Pressure Water Line Polyethylene Tubing as a "Form" to hold the Loops in a Circle Shape. This Tubing must 'slip-over' the Coax Cable's "F" Connectors.

THE LOOP ANTENNA "HOOK-UP":
* Slide the Coax Cable Loop Antenna Element into the Plastic Tubing.
* Connect your Coax Cable Loop Antenna Element to the LOOP-HUB {Splitter}.
* Connect your Coax Cable Feed-in-Line to the LOOP-HUB {Splitter}.
* Install the "F" Connector to PL-259 Plug to the 'other end' of your Coax Cable Feed-in-Line and Connect to the your Radio/Receiver.
* Shape and Position your Loop Antenna Element.

CAUTION: When Installing the Coax Cable "F" Connectors into the "F" Connectors of the LOOP-HUB: Be careful to make sure that the Center Wire is NOT Bent and Shorted-Out.

SIZING: This is a Low Noise SWL InDoor Loop Antenna that allows the 'changing' of the Loop Antenna Element for the Coverage of different Shortwave Bands. These Loops are 'cut' "Sized" to roughly One Tenth of a Wave Length (1/10WL)
* Twenty-Five Feet (25 Ft) roughly the 120 Meter SW Band
* Twenty Feet (20 Ft) roughly the 90 Meter SW Band
* Fifteen Feet (15 Ft) roughly the 75 Meter SW Band
* Twelve Feet (12 Ft) roughly the 60 Meter SW Band
* Nine Feet (9 Ft) roughly the 41 Meter SW Band
* Six Feet (6 Ft) roughly the 31 Meter SW Band
* Five Feet (5 Ft) roughly the 25 Meter SW Band
* Four Feet (4 Ft) roughly the 19 Meter SW Band
* Three Feet (3 Ft) roughly the 13 Meter SW Band
The above Lengths and SW Bands are 'based' on the low

cost common {RadioShack} TV type RG-59 Coax Cable with
a Velocity Factor of 0.66.
NOTE: If you use RG6 "Quad Shield" Coax Cable that has
a Velocity Factor of 0.78 to 0.82: Then every thing would
shift down one SW Band 120M>90M, 90M>75M, 75M>60M, ETC.

PACK-AND-GO "TRAVEL" LOOP ANTENNA:
This Design-Set-Up makes for a 'portable' Travel SWL Loop
Antenna that can be Taken-Down and Put-Up in a Minute or two.

MEGA-SIZED FIFTY FOOT LOOP FOR THE AM/MW BROADCAST BAND:
Take a Fifty Foot (50 Ft) piece of Coax Cable and Mount
it OutSide Doors
- 540 kHz to 1700 kHz with a MidPoint of 1120 kHz
- Fifty Feet (50 Ft0 [1/10WL] VF=0.66 using RG59 Coax Cable.
- Square shape 12.5 Feet per Side with 17.5 Cross-Arms.
- Round shape 16 Diameter Circle.
- Coax Cable Lead-in-Line 5-10 Feet.
This is roughly the "Sizing" for the AM/MW Broadcast Band
For DX-Peditions throw a 50 Foot Coax Loop Antenna Element
Over a Tree Limb about 15 Feet High and stretch-out the two
bottom side to form an Equilateral Triangle 17 Feet on a side.
Hook-Up everything and sit-down and Listen :o)

Are you aware that you have to use a 1/4 wave lenght impedance transformer
(matching line) on 20 meters?
This is the text from the original manual:

Symptom: High SWR on 20 meter; other bands OK.
Look for: Missing matching line. Antenna not properly tuned. 20 meter
radials not present or wrong length. Consult instructions for tuning and
radial information; install matching line RG-11 75 ohm coax, 11 ft 4 in
(345.4 cm) if solid dielectric, 13 ft 6 in (411.5 cm) if foam type.

Many examples exist for current drops in distributed networks. That's one thing that makes circuit analysis invalid for distributed network problems. The series current is NOT the same value everywhere in a distributed network. Asserting that there is no such thing as "current drop" in distributed networks simply indicates an invalid choice of models.

How much current drop is there at 440 MHz in 100 feet of RG-58 between the source and a 50 ohm load? Answer: A 20 dB power drop equates to a 40 dB current drop.

I used a similar idea for my 3.3' and 7' loops constructed from 3/4" CATV hardline. A CATV junction box for the termination and wideband preamp ( no tuning) and the standard 3/4" CATV connectors.

If you make clear what you mean and why you think it makes sense
there's nothing wrong with using non-standard terminology if it
aids communication. If you just pull it out of the air as if it
were a normal technical term that all technical people use, then
you're just gassing nonsense. I expect someone on this newsgroup
will start talking about "voltage flow" next.

I get the general idea of what type of relay to look for but where do you
get these???

And if I use banana plugs/binding posts at my entry points do I have to
install them in insulating material?? Something about running ladder line
through binding posts installed in a metal cabinet doesn't sound right....

> 40 dB current drop.

Cecil,

You seem to like the "Roach Motel" theory of current flow. The electrons
check in, but they don't check out.

Here's a clue.

Conservation of charge is every bit as fundamental as conservation of
energy. Current does not just disappear. So what happens in your abused
RG-58 case?

Answer: this is not a simple series circuit.

At every point along the line the current splits between continuing down
the line and shunting to the other half of the transmission line. When
the line is lossless, the shunting is purely reactive, and no net
current flows. However, when there is loss in the line, there is a small
phase shift along with the attenuation, and net current is shunted.

The "circuit" model, as you like to call it, is every bit as valid as
the "distributed network" model. However, due to the distributed time
and space considerations in a transmission line, the "circuit" model is
mathematically intractable for many applications.

The physical reality remains the same even if we cannot easily do the math.

Oh, by the way, in a constant impedance environment the current change
corresponding to a power reduction of 20 dB is also 20 dB, not 40 dB.

The banana plug receptacles typically have a plastic collar to keep
them from touching the cabinet. If you'd rather go with ceramic
feedthrough insulators, they have them in all sizes at Surplus Sales
of Nebraska. Pricey, but they got 'em.

Jack Painter wrote:
"Here is where you are mixing apples and oranges because ground loops and lightning protection are not related."

A ground loop is a potentially detrimental condition due to two or more points in an elewctrical system that are nominally at ground potential being connected by a conducting path.

A ground loop may provide a common impedance which couples energy between two or more circuits. Strength of the energy in the electrical circuits is immaterial in a current loop so long as nothing breaks down. Response to the excitation is the same.

A lightning strike is a huge noise injection. Techniques for noise reduction and testing are
also applicable to lightning suppression and may be tested with weak noise signals. I know from personal experience.

It is desirable to avoid common impedances which can couple lightning from one circuit to another, as a "ground loop" may.

Ground connections for protected equipments can be made with individual wires between each of the devices and a common ground point to avoid ground loops. This is not always practical.

It is usually practical to enclose devices inside a conductive enclosure, then to low-pass filter and surge protect every wire which penetrates the enclosure.

A screened room can serve as both noise and lightning protection, for example.

Best regards, Richard Harrison, KB5WZI

Richard,

I am not sure why you think there is a violation of Kirchhoff.

The current law is unchanged. The analysis of the voltage law is much more complicated, but not incorrect.

The situation is not really any different than the use of retarded potentials for radiation. One must carefully keep track of the loop voltages with consideration for time and space differences, but there is no fundamental difference in the physics.

For distributed networks, the Kirchhoff voltage calculation is difficult (intractable). It is not impossible, but it is unnecessary due to the existence of the much more friendly transmission line formulations.

Hi Richard,

No one can argue with Kraus and Terman
or anyone else on this. What is "debatable"
is: at what point does radiation resistance
become too low - where high current losses
cancels any gain achieved by the tight
coupling. This is JMO, of course.

Tom Donaly, KA6RUH wrote:
"I know there are people in the past who have attempted to characterize antennas as transmission lines."

True. You can include Terman among them.

Terman discusses antenna current distribution on page 866 of his 1955 edition:

"Under most circumstances the losses are sufficiently low and the ratio of wire length to diameter sufficiently great so that to a first approximation the current distribution can be taken as that for a line with zero losses; it then has the characteristics discussed in Sec, 4-5."

Sec.4-5 is found on page 95 and is titled: "The Effect of Attenuation on Voltage and Current Distribution - Lossless Lines".

Sec. 4-5 is in Terman`s chapter on Transmission lines. Obviously an open-circuit antenna has the same current distribution as an open-circuit transmission line, and for the same reason.

Best regards, Richard Harrison, KB5WZI

Hi MK,

When I stated:
> > (it's not a dummy
> > load as one would generally deduce from
> > the above description)
I wasn't joking. The fact that you've never known a vertical antenna to behave in this manner, is not surprising.

The purpose of my experiment was to investigate the possibility of loading (shortening) an element while still maintaining a relatively normal BW.

Avoiding parallel wires and coils, the resulting loading system is what I call E-field loading (perhaps a poor choice of terms) - a method of conductive loading that resulted in reducing the off-resonance reactance in the FP. I suspect it is effecting the susceptance of the voltage loop in some way. The unexpected bonus, of course, was a reduced susceptibility to electrical noise.

The E-field and the H-field are inseparable in an EM RF wave.
If the H-field (current component) is flowing, then so is the
E-field (voltage component). If the E-field (voltage component)
is dropping due to radiation, then so is the H-field (current
component). That's one of the differences between a distributed
network RF wave and a DC bench circuit.

And how could we possibly have a Power Flow Vector without the
voltage flowing along with the power and the current? :-)

Probably best we distinguish between "flow", and propagation, before we digress into discussions of "standing wave propagation". ;-)

Yes, I wasn't suggesting to shorten the banana posts to the metal, thus shortening the two antenna leads as well.

I was more thinking about the suggestion of keeping ladder line away from objects, not nailing it directly to the siding of your house for example.

That suggests that this unshieleded line might be influenced by objects close by. And along those thoughts I was wondering if bringing both lines within fractions of an inch to a common ground, the metal box, might be a good idea.

You place another element closely (behind usually) to the driven element
such that with a
'critical coupling' the feed impedance increases to the desired level.
It is beyond me why antenna manufactures still ask people to match to a low
impedance
which provides losses, when the antenna can be provided with a feed
impedance of 50 Ohm !

I must be in error ofcourse with the above statement as everything is
already known and utilised

May I also point out that if you allow elements to vary in diameter and
height and still keeping to
a .1 boom length, gain increases until ultimately the elements form a
combined parabolic shape
and progressively place rearward radiation energy into the forward direction
until the ultimate is reached,
where there is no radiation to the rear and F/B is absent. I would remind
you that the top element is
going to be designed to be disconnected and connected to ground to
determine impact on static noise.
It is also my intent to string nylon from one end of the elements to the
other, progresively tightening it
until a suitable bend or bow is put in place such that the beam width
narrows to somewhere in the
range of 30 degrees. (ala point to point to get highes gain together with a
lower take off angle)

I do have a fold over tower by the way over 1/2 acre of clear ground with
embedded wire screen
and I am surrouded by sloping farmland with Drummond soil..The 1 inch
hardline is routed undeground.
The above experimentation is why I have so much fun with antenna
experimenting where in other
ways the experts would say it is useless to try before I even put my shoes
on.

You don't even have to go as far back as Terman. Reg Edwards bases his
antenna programs on the transmission line behavior of antennas, and
his programs do as well as you'd want. That's one way to look at
antenna behavior. It's not the only way, and it doesn't mean that
Cecil knows what he's talking about when he espouses the theories
he made up in his head out there in the hot Texas sun.

Source record: 87591

"Richard Harrison" <richardharrison@webtv.net> wrote
Jack Painter wrote:
"Here is where you are mixing apples and oranges because ground loops
and lightning protection are not related."
--
A ground loop is a potentially detrimental condition due to two or more
points in an elewctrical system that are nominally at ground potential
being connected by a conducting path.

Ground connections for protected equipments can be made with individual
wires between each of the devices and a common ground point to avoid
ground loops. This is not always practical.

It is usually practical to enclose devices inside a conductive
enclosure, then to low-pass filter and surge protect every wire which
penetrates the enclosure.
--

Hi Richard, had I thought that was a controversial statement, I could have
elaborated that elimination of ground loops is normally a radio frequency
interference issue, and the creation of at least one ground loop is a design
requirement in residential lightning protection. The two are not usually
discussed together unless a conflict ocurrs, but I see your point.

It is indeed a requirement to individually bond equipment to the single
point station ground...and yes, practicality allows certain clusters of
equipment to be common bonded within their enclosures as you commented. But
the one place where a ground loop *must* be installed is in the station
ground to electrical service ground bonding. Proper station design requires
these never be far apart from each other in the first place, but we are
talking about residential stations, and close proximity between them is
rarely possible.

Telecom stations that cannot individually bond thousands of cards or even
hundreds of racks use high voltage isolation transformers and/or fiber optic
isolation from station ground entirely. Residences typically have neither
close proximity to AC service ground, not the financial ability to utilize
fiber or other HV isolation, so living with at least one ground loop is a
requirement. This has been reported to cause problems in some zero-volt
ground reference computing equipment, and isolated grounding is authorized
under certain conditions for that case only. I have not seen comments about
radio frequency interference from ground loop(s) caused by lightning
protection design. If they occur, perhaps they are easily choked with
standard RF control devices. I use those extensively anyway, so maybe that
chokes any ground loop problem, if one ever existed.

Thanks for your comments as always,

Jack

> Cecil knows what he's talking about when he espouses the theories
> he made up in his head out there in the hot Texas sun.

Tom, I think I get it now. Here is what I have learned from you.

1. Even though the only difference in the voltage and current equations
for a transmission line is one constant (the variable terms yield
exactly the same relative magnitude, phase, and attenuation
for the voltage wave and the current wave) and the decrease in the
voltage and current between the source and the load is exactly the
same percentage:

While the voltage reaching the load suffers a 10% drop, the current
does not suffer a drop. The current only suffers a 10% decrease.

2. While the voltage wave and current wave are traveling exactly the
same path in the same phase at the same speed from the source to the
load:

The current wave flows to the load but the voltage wave does not
flow to the load. The voltage wave only travels to the load.

Did I get it right?

> (345.4 cm) if solid dielectric, 13 ft 6 in (411.5 cm) if foam type.

AH-HA! Since the antenna didn't have the matching line with it, I put a
1/4 wave stub of around 16' 6" on it, which is quite off from the actual
value that they want. It is solid dielectric, so it is off by over 5 feet!

Thanks very much for the clarification of my problem.

For the original question that I had, I am going to put the cap in
series with the 30 meter coil, as after scrutiny of the parts list, that
is the only way I can see it fitting in the assembly.

><--Both tax classifications (ie 501C3) business...
>
All types of non-profit corporations need to follow the IRS tax
regulations, as well as corporate law for the state in which they are
incorporated. They also need to follow commonly accepted accounting
practices, including an annual review of their finances and procedures
by an outside CPA.

Any non-profit type corporation can accept donations, but only
donations to a 501(c)(3) charitable non-profit are tax deductible for
the giver, and certain other benefits and programs are reserved for
501(c)(3). Grants are usually only available to (c)(3)s.

The flip side is that the standard for becoming and remaining a
501(c)(3) is more difficult, and they are scrutinized more carefully
by the IRS.

The vast majorities of their activities need to be charitable (for the
community, not their membership), educational, religious, or
scientific.

Other types of non-profits (there are at least a dozen other types) do
not need to meet such a high standard for their activities. Many would
fall under 501(c)(7), which is "recreational or social" clubs.

There are also restrictions on payments to Board members.

I suppose in theory that a for-profit business could accept donations,
but there would be no tax deduction for the giver, and the business
might have to pay taxes on it as income. Doesn't make sense, but it is
not illegal.

Cecil,

I am glad you agree with me, but unfortunately my message was apparently lost on you.

No one has ever discussed simple series DC concepts except you. Kirchhoff laws do not require series circuits or DC.

The simple concepts work perfectly well, even on transmission lines. However, setting up and solving problems is mathematically complex, so everyone uses the transmission line formulations. There is no new physics needed. The electrons and waves don't care about math models. (I think I heard something from you along that line a few times.)

There is nothing wrong with the theory. It works perfectly well on "RF distributed networks". What is wrong is calling a lossy transmission line a "simple series circuit" and then misapplying the theory.

Could not get it to work. Below is my NEC2 code ( heavily segmented as it is easier to figure out where to place the source and load). What am I doing wrong? Resonant on 7.25 MHz before extending the antenna. Approaches resonance on 22 MHz, when extended, with very high series L. A 40 m dipole is resonant on the 3rd harmonic anyway so all you are doing is isolating the extra 1/4 wave by placing a very high impedance at the quarter wave point. I guess I missed something, be interested in any comments.

Regards,

Frank

PS should I have used an actual helix? Very tedious to structure with code, although have done it in other models. Noticed that the current in and out of the coil is vastly different when compared with using the lumped element model.

> What is wrong is calling a lossy transmission
> line a "simple series circuit" and then misapplying the theory.

That's exactly my point, Gene. I think you missed it. What is
wrong is assuming a simple one-way series current flowing through
a point inductance in a *standing-wave* mobile antenna containing
a one foot by one foot 75m *bugcatcher* coil that occupies more
than 60 degrees of an electrical 1/4 wavelength.

The original argument originated over on eHam.net. Tom, W8JI
said there is no change in current from end to end in a loading
coil. Yuri disagreed. Everything else is a fallout from that
original argument.

The lumped point inductance will definitely not give the correct results.
The coil needs to use the helix feature of EZNEC+ 4.0. I constructed an
8-sided coil out of segments in EZNEC 2.0 and the results can be viewed at:

http://www.qsl.net/w5dxp/octcoil2.gif

The dimensions and inductance are not perfect but the idea is perfectly
clear. There's 0.11 amp at the bottom of the coil and 0.57 amps at the
top of the coil. By playing with lengths of wire and frequency, I've seen
the current at the bottom of the coil as low as 0.005 amps while the
current at the top of the coil was about 0.6 amps.

>I am not sure why you think there is a violation of Kirchhoff.

Hi Gene,

Kirchhoff does not allow for circuits of dimensions that are
appreciable size with respect to wavelength. Simple reason is that
you should then shrink down the unspecified lead length (for voltage
law) into the stray, equivalent and dimensionless components. This is
outrageously flaunted in this group, and then couched as examples of
modeling failure (when it is in fact modeler - the human component -
failure).

This is the "intractability" you speak of - the neglect of the proper
rendering of the network in dimensionless terms.

Yes, use an actual helix. If it will help, download octcoil2.ez from my
web page by clicking here:

http://www.qsl.net/w5dxp/octcoil2.ez

For this particular case:

http://www.qsl.net/w5dxp/octcoil2.gif

a lumped point inductance gives bogus results.

you might want to just use a 1/4-wave vertical or a dipole
beams are good if you aim them where you want to hear
but if they're not aimed they are worse than a rubber-duck.
the gain in the forward direction is at the expense of other directions.

Still doesn't say too much...

I suspect it is effecting the
> susceptance of the voltage loop in
> some way.

Ditto...But I don't know how long the vertical is. Being you need
loading, I'll assume it's shorter than a quarter wave...Dunno...This
just doesn't really add up to me...I've fed verticals in many points,
at the max current, or max voltage points, or in between, and have
never seen this to effect noise pickup. Again, the only thing I've
ever seen to reduce noise, *and* keep the same pattern, was to
increase loss.

The unexpected bonus, of
> course, was a reduced susceptibility

> to electrical noise.

Due to extra losses? If you reduce susceptibility to far field electrical noise, you are also reducing the desired signals at those same angles. Rf is rf...What am I missing here? Myself, I consider the so called "low noise" antennas to be old wives tails...
Even the shielded electrostatic versions, for the most part. IE: shielded loops, etc...They are no more quiet than any other well balanced loop made of normal wire windings. The shielded design is not to magically reduce noise, it's to ensure balance. I'm not trying to be ornery, but so far, what I read is not flushing to *me*...But I don't believe in "low noise" antennas. To me, low far field noise compared to another vertical antenna at the same angles and same polarization, means increased loss somewhere if the pattern hasn't changed. :( MK

Hummm... It *should* have worked just fine. Besides being lousy to
solder to, there is nothing wrong with a foil shield. Thats solid
coverage, and better than strands of wire. The coax shield for a SW or
MW loop should be fairly non critical. The only purpose is to ensure
balance. MK

"The Results were very poor" is not very much information to go on to
any conclusion or solution.

Maybe he was expecting more output from the loop than he got. A shielded
loop that is not very large is not going to have a big output. Maybe he
screwed up and did not have a shield gap.

Most of the available implementations of NEC-2 include the ability to
generate a helix. Look for information on a 'GH' command.

Yes, if it's from a single source, and it will also tell him which direction it's in. Well, it's bidirectional, but common sense will tell which way it probably is, if you already know about the fence...But yes, most likely a small loop would take most of it out. Maybe even all of it. The nulls on a good balanced loop are sharp and deep. I know my loops can take a single noise source right out of the picture. Or an undesired station for that matter if it's ground wave... MK

Thanks for the info. Should have studied the NEC 2 manual more carefully.
It is on page 20 with no card picture.

Regards,

Frank

Sorry that was really dumb, did not think before I posted the response. I
was certainly aware that the currents in, and out, of a lumped element
inductor are the same. I had recently modeled a short monopole with a
physical, octagonal, helix (Now I learn about the GH card!). The difference
between the lumped element and distributed inductor is significant, although
the gains are almost identical from both models.

Some time ago, I generated an 8-sided coil for EZNEC 2.0. It was a
lot easier than I thought at first. Here's one turn of dia=13" at
about one turn per inch. Note 'y' always equals the x value from two
lines up.

x y z

Hi Frank,

You've hit the nail on the head (although I've seen it claimed it
makes a 12dB difference!).

Rarely do we get any practical correlation from this "sky is falling"
oops "current is dropping" argument.

# 1337. Re: Current in loading coil, EZNEC - helix

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-26 15:28:31 UTC
From: Gene Fuller <W4SZzzzzzz@att.net>
Message-ID: <z2ufd.31630$OD2.9354@bgtnsc05-news.ops.worldnet.att.net>
Source record: 87532

Cecil,

I am fully aware of the "original argument". To confess my bias, I agree with Tom D. and Tom R. There is no "current drop" ever, and there is no current change in an ideal inductor. W8JI explains in some detail why real coils show different currents at each end.

My response was aimed at your little demo circuit. Let me share one of my own.

```
-----------------------------------------------------
+ | | |
------------ ----------- -----------
| | | Ra | | Rb |
| 1 V DC | | 100 Ohm | | 100 Ohm |
| 20 mA | | 10 mA | | 10 mA |
------------ ----------- -----------
- | | |
-----------------------------------------------------
```

The source provides 20 mA, but Rb passes only 10 mA. Would you call this a "current drop"? Most people would say that the total current has simply divided into multiple paths.

Your RG-58 transmission line example is no different. The current from the source is not lost or "dropped". It simply finds other paths in addition to the "load" to return back to the source. Antennas and loading coils exhibit the same phenomenon.

The error is in considering the transmission line as simply two non-interacting conductors that somehow magically enforce a fixed impedance, Zo. If the conductors did not interact there would be no fixed impedance; it would not be a transmission line.

Your reference to simple DC analysis ignores the interaction between the transmission line conductors. If you modeled the problem correctly you would need to account for the leakage current. There would be no "current drop" and no mystery.

The laws of electromagnetics do not change in any fundamental way until relativistic and/or quantum considerations come into the picture. There are "different horses for different courses", and there are different "computationally preferred" approaches to different electromagnetic configurations. Often there is best choice for practical reasons, but that does not make the more difficult computation wrong.

Richard,

In simple terms Kirchhoff's loop law says that if we correctly add all of the potential changes around a closed loop we do not end up with a different potential than we had initially. (It does not say just how to handle the computation.)

As you may know, there are some non-conservative systems in which this behavior is not true. Traversing around a loop exhibits a spiral behavior. The measured quantity continues to increase (or decrease) with every pass around the loop. Kirchhoff's loop law says this sort of spiral does not happen in an electrical circuit.

Computation is "intractable" for distributed RF networks, but the principle is still valid.

Your helix is far more elegant than my octagonal structure, where each turn is in the same plane, and a 90 deg segment then connects to the next turn.

I have just experimented with the GH card -- combined with the GM card. It appears to be an excellent method of constructing a helix. I have not seriously attempted to determine the optimal segmentation, but as long as the segments are less than or equal to the turn spacing the results seem acceptable -- as with parallel transmission line models. I have also attempted to maintain the same segmentation on wires external to the helix, and to use the same wire size. While these structures are interesting, from the point of view of analyzing current distribution on an antenna, there seems to be very little difference in the actual performance of an antenna modeled with lumped element components. What I have learned (as mentioned in a previous posting) is that it is possible to predict, with a fair degree of accuracy, the actual inductance of a helix.

Hi Richard,

Cannot see where anybody could get a12 dB difference, since you can only model a lumped element inductance, you could not build it to test the performance. I have spent many hours this past week modeling short, loaded, monopoles, over a perfect ground -- triggered by the previous thread -- just to see what results I could get. An 86.5" vertical, center loaded, with a lumped element inductor resonating in the 21 MHz range, exhibits an input impedance of 20.91 Ohms, and a maximum gain of +4.754 dBi. The same antenna with a distributed 12 turn helix, of 2.5" diameter, and 6" long, has an input impedance of 18.98 Ohms, and a gain of +4.783 dBi. The helix alone has a gain of -25 dBi. Transcribing the NEC output file to an Excel spread sheet produces some very interesting current plots.

73,

Frank

Art Unwin wrote:
"You place another element closely (behind usually) to the driven element such that with a "critical coupling" the feed impedance increases to the desired level."

That`s not the way it works. More coupling lowers the feed impedance.

Check under "Close-spaced Arrays -- Super-=gain Antennas" on page 906 of Terman`s 1955 edition:
"A characteristic of all close-spaced arrays is that as the ratio of size to antenna gain is reduced, the radiation resistance also goes down;---." The Yagi antenna of Fig.23-39, and the corner reflector, represent almost the best that can be achieved in a compact array."

Notice that Terman said "almost". There`s always hope, but looking for more gain by element spacing changes has been thoroughly investigated. This is akin to to drilling in a field which is already overdrilled in the search for oil.

Moving elements closer together brings the radiation resustance down. The elements don`t know if a coupled element is ahead of the driven element or behind it. It brings the drivepoint impedance down for the driven element. Impedance adjustment is done through transformation.

Best regards, Richard Harrison, KB5WZI

WNTU4 wrote:
"Now I know I can`t attach ground to gas line."

The gas line is likely grounded on the house side of the meter. Stoves, etc. have e3lectrical appurtenances which otherwise might shock you..

The supply side of the meter is likely nominally insulated to avoid overloading the cathodic protection rectifier which maintains a fraction of a volt on steel pipes and other gas supply equipment. This tiny potential ensures that ions flow toward the apparatus rather than away, which would erode the stuff away.

You only must avoid shorting out the cathodic protection potential. Easy since its insulation is already very poor. Pipe dope has cracks. The rectifier has a large ground bed for its return. The rectifier has leaky arresters, etc. It`s no real problem to have a very near ground rod. The gas pipe is subjected to plenty of lightning current during thunderstorms.

Hello,

During my time surfing the web I have found a number of useful amateur radio antenna links. I would like to share some of these with you to add to your bookmarks or favorite links. For the online calculators I've found that if you save them in Internet Explorer as a web archive .mht file you can use the calculator offline because it is an HTML file. I hope you find these links as useful as I have.

> loading, I'll assume it's shorter than a quarter wave...

Hi Mark,

Yes, its vertical height is 23 ft. It is elevated
6' above ground with elevated horizontal radials.
The input Z at the junction of the radials and DE
is 50 ohm j0 with no matching system. There is
a current un-un at the feedpoint, thus no
common-mode, and the Tx line is 1wl electrical.

The experiments with this type of loading was
begun around '95 - '96, and this vertical antenna
was erected in '98. It has been through near I/2
solar cycle, and all seasons. Time has a way of
dispelling illusions, and don't think for a moment
that I ignored the "loss" question.

> To me, low far field noise

Do not assume all noise is the same or
that all originates in the 'far field' as EM
particle-waves.

> oops "current is dropping" argument.

Asserting that the argument is about any practical correlation is
a diversion of the issue. THE ARGUMENT IS ABOUT THE CURRENT IN A
LOADING COIL, not about the radiation pattern. The radiation pattern
is completely irrelevant to the argument. One side says the current
is absolutely constant except for radiation. The other side says it
is not constant (except for special cases). An electrical 1/4WL loaded
mobile antenna is not one of the special cases.

Nice attempt at changing the subject - didn't work.

In the process of learning why the superposed current is not constant
through a loading coil in a standing-wave antenna, you will also learn
something about standing-wave antennas in general.

YOu don't usually use 1/4 verticals for over head passes of the sats. They have a big null overhead. Use a horizontal dipole or beter a dipole over a reflector. Think about 3/8 wavelength is the best distance for the dipole over the reflector but need to check that .

> real coils show different currents at each end.

So do I, Gene. Have you looked at my web page? A standing-wave antenna contains standing waves. The forward and reflected currents superpose. If there is any phase shift at all through a 75m bugcatcher coil, the current at the bottom and at the top will NOT be equal even if the forward current through the coil is constant and the reflected current through the coil is constant. If you disagree with me and agree with Tom, you are saying there is zero phase shift through a one foot by one foot bugcatcher coil. Do you really want to assert that?

How can there possibly be a current drop across a dimensionless point? The fact is, a dimensionless point inductance does NOT and can NOT exist in reality. So are more interested in playing games in your mind than you are in the real world? The argument is about real world 75m bugcatcher coils, not ideal inductances that exist only in someone's wet dream.

Your example is a circuit, not a distributed network, and is therefore irrelevant to this discussion. Distributed networks behave different enough from lumped circuits that the lumped circuit shortcuts just don't work on distributed networks. Why you and Tom want to force your lumped constant concepts unquestioned upon the field of distributed network problems is beyond me.

> Your RG-58 transmission line example is no different. The current from
> the source is not lost or "dropped". It simply finds other paths in

> loading coils exhibit the same phenomenon.

Some of the power radiated from an antenna does NOT return to the source. It may even escape to outer space. Power lost from the system causes a current drop. In fact, it is hard to separate the H-field from the E-field for RF. I am amazed how you guys have been seduced by your math models. Reality is supposed to dictate math models, not vise versa.

Don't let the logical diversions throw you. The argument is, and always
has been, about the current in a loading coil, not about the radiation
pattern. The radiation pattern is absolutely irrelevant to the argument.

Cecil,

Until you try to understand the difference between current in a
conductor and power radiated into space, this is a hopeless debate.

There are several important relationships among charge, current,
E-fields, voltage, and H-fields. However, current is not the same as
H-field, voltage is not the same as E-field, and charge is not the same
as a radiation field.

Back to Physics 101 for you.

Gene Fuller wrote:

> Cecil,
> Until you try to understand the difference between current in a
> conductor and power radiated into space, this is a hopeless debate.

Isn't there a direct correlation between current in a radiator and
power radiated into space? Assuming the conservation of energy
principle holds, power radiated into space reduces the current
in a radiator (since the ratio of the forward voltage in a radiator
and the forward current in a radiator is proportional to the power
available). Sorry to say, Gene, the current drops in proportion to
the drop in the voltage in a fixed Z0 environment. If a terminated
traveling-wave antenna were 100 wavelengths long, it's current at
the termination would be a small percentage of the source current.

Hint: ExH = Poynting Vector power and the E/H ratio is constant.

Until you give up on the possibility of a point inductance
existing in reality, this is a hopeless debate. I can't believe
you are defending an indefensible model of reality, so I can only
conclude that you are defending the irrational premise of a friend.
You and I are obviously on the same side of physics and you are to be
commended for being a good enough friend to that un-named someone
to set aside your knowledge of physics and side with his/her
irrational premises, arguments, and conclusions. The reason that
I don't have any such friends is that I wouldn't accept that kind
of support if I was wrong. But I do understand it is human nature
to respond in such a manner.

The ARRL Antenna Book and various other publications give the
characteristic impedance of a horizontal single-wire TRANSMISSION
LINE over ground as:

Z0 = 138*log(4h/d) where 'h' is the height and 'd' is the diameter

Doesn't a "horizontal single-wire transmission line over ground"
sound a lot like a dipole made out of #16 wire 24 feet above ground
having a Z0 of 600 ohms?

If you ignore that question, I will assume your position on this
subject has everything to do with friendship and nothing to do
with physics. Actually, like Richard C. and I, I don't think
you and I have any argument about physics.

# 1360. Re: Gain per unit length of boom

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-27 00:13:56 UTC
From: "aunwin@insightbb.com"
Message-ID: <8LBfd.253236$wV.135788@attbi_s54>
Source record: 87555

No Chuck, that is not going to happen.When you are an experimentor you don't have to be hindered by diminishing returns as it is the chase that is the most rewarding part. There has been many oilfields and silver mines that have been abandoned ONLY because of diminishing returns which is usually because of greed and not for the joy of doing what one likes to do.
For those who quote from books without a real understanding of what is being said are doomed to only quoting books
without the self determination needed to explore new frontiers. A book is to be used to explore the past but to explore the
future one has to avoid generating bed sores and procrastination and explore what the future holds for those who are willing to move without fear of failure.
On diminishing rear radiation, that can only go so far as the efficiency relates heavily to the ratio of the element diameters
relative to spacing of elements on the reflective medium, so one can easily be disapointed when stacking two 2 element beams using only 4 elements instead of the many required for a "dish", but the low take off angle can still be reproduced as well as a narrow beam with extra gain if the corrective reflective contour can be obtained. Sure beats argueing about current decline versus current drop versus current flow or what pack of wolves to join.
By the way, do you know if dish antennas suffer from static like dipole arrays? I would think they would be immune
but I really don't know.
Regards
Art KB9MZ XG

Ask him to please produce the posting. A 100% difference between
lumped element and distributed loading wouldn't produce much of
a difference in the radiation pattern. Sorry Reg, most of the
radiation happens below the coil, whether lumped or distributed.

I've but 6 BTV s together past wirh no problem, now I have one with new one. It's fine on 10, 15 ,20 and 40. But 3 t0 1 on 30 and 7 t0 1 on 80. Dimensions and traps are right. Tried adjusting 30 meter coil per their instuctions and nothing changes even though a 1/4 inch change is supoose to affect it 5000Khz! I used penetrox from a klm antenna when assembling it. Does anyone know if that causes problems. Dont know why 40 would be ok and 30 not. Checked to be sure they didnt give me wrong trap and they did not. Advice please.

Tks,

Gerry fjx1 @aol.com

But that is totally untrue!
He was invited to Congress to pass on information that was spoken about
at a Vietnam veterans get together that occured a few weeks earlier.
He at no time admitted to first hand knoweledge on the veracity of the
cruelty claims made at that convention.
And I do not believe the GOP claims otherwise.
He was at that time a veteran himself as well as being against the war but
if I remember correctly many
showed their feelings by crossing the border, where as he protested using
the ideals that all fight for
.....free speech .
Bush chose the service aproach that many tried for and was successful, both
he and Kerry
were just part of those times and neither should be villified.
If one has first hand knoweledge then he has the right of free speech, when
one uses
free speech without true knoweledge and for his own means then he/she
betrays the ideals for
which one fights for.

Hi Gene,
you may never have had an exchange with Cecil. Cecil will use
any tactic in the book to "win" an argument, the more illogical
the better. Moreover, he's absolutely dogged in his determination to
have the last word, going so far as to make completely idiotic posts
in the hopes that his opponent will quit in disgust. Unless you
want to engage in a 500 post exercise in absolute lunacy, you might
want to ignore Cecil altogether, as several of us do.

# 1367. L-match tuner with off-center dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-27 03:04:46 UTC
From: pdrunen@aol.com
Message-ID: <20041026230446.13148.00003679@mb-m28.aol.com>
Source record: 87562

Hi Group,

I picked up a nice AEA AT-300 tuner. It's a bit different than anything I used before from MFJ. MFJ has the one lnductor with two tuning caps where as the AT-300 has two inductors and one tune cap.

I connected me off-center dipole, which has 80 feet on one leg and 40 on the other and is fed with a 4:1 balun at the input and 50 feet of RG-58 down to the tuner.

I also have a MFJ-269 antenna analizer and would tune the AT-300 using the reading for the impedance and shooting for 50 ohms with no reactance as indicated by the MFJ readout.

Well, now, it was very hard to tune and I found that it was more like trial and error.
So, is there a method of set up to maybe select one inductor for best 50 ohm resistive and then select the other for best minimum reactance and then tune out the VSWR with the capacitor?

De KJ4UO.....

Paul

Tom,

Every few months I suffer a complete breakdown in common sense, and I engage with Cecil.

You may recall the record-setting threads on Steve Best vs. Walt Maxwell. Then there was the endless debate on optical reflections, built around Cecil's gross misinterpretation of the Melles-Griot Optics Guide.

You are right; it is time to go back to my cave for a while.

One wonders if you are capable of anything except ad nauseum ad hominem attacks. So far, my grouchy ten-year-old grand-neice could have made your postings.

Tom, so far, you have offered absolutely nothing of a technical nature to prove me wrong. That's a big clue that you have nothing to offer. If you can easily prove me wrong, why haven't you? If you can prove me to be technically wrong, I will yield to you in respect. However, until I am proven wrong or sentenced to house arrest, you can expect me to have an attitude similar to Galileo's up against the Catholic priests. Is one iota of proof too much to ask?

Balanis says you are wrong! Kraus says you are wrong! EZNEC even says you are wrong! Today I created a one foot high helical antenna that packs 90 electrical degrees into one foot. The current at the bottom is one amp. The current at the top is zero amps. Want me to send you the EZNEC file?

Here's your chance. Exactly what is the difference between a 1/2WL #16 single-wire transmission line 24 feet above ground and a #16 1/2WL dipole 24 feet above ground? Please be technically specific. Your feelings don't matter.

It seems to me a patch antenna for 150 MHz either be huge or will have very low efficiency.

If you need small size, how about multi-turn wire coil wound on ferrite rode?

(I hope I do not steer you too far from what you thought.)

Andrey

I hope you remember that I didn't agree with either side. I stated that
they were two inches apart and neither one of them would budge one inch.
Dr. Best denied there was any such thing as interference at a match point.
At the time, Walt didn't understand the pseudo S-parameter analysis that
Dr. Best was using.

> Then there was the endless debate on optical reflections, built
> around Cecil's gross misinterpretation of the Melles-Griot Optics Guide.

The "lost" reflected power joins the forward wave? That's what they say.
There's no way for reflected power to join the forward wave without changing
direction. Seems I am up against the Spanish Inquisition. Is "Fuller" Spanish? :-)

> You are right; it is time to go back to my cave for a while.

I am always quick to admit an error, like the 20dB vs 40dB error I made
yesterday. Nobody has offered one iota of technical proof that I am wrong.
I didn't realize that the science of physics depends on a newsgroup democracy.

I find it amazing that the only argument you guys can come up with is
an ad hominem attack. That's usually the last resort of someone who has
lost the argument. If I am so technically incorrect, is one iota of
technical proof too much to ask? It is, of course, if this is a good-
old-boys EM religion discussion rather than a technical discussion.

Art Unwin wroyte:
"Then the book is incorrect assuming you are using statements
correctly."

I included page numbers to make it easy to check the accuracy of my
translation.

Art said elements are "critically coupled". Critical coupling is defined
as maximum energy transfer at the resonant frequency.

Coupling additions (more loads) to a feedpoint lowers the impedance
unless additional measures (transformations) are taken. Coupling more
loads to a feedpoint is tantamount to paralleling resistors. Terman is
right.

Best regards, Richard Harrison, kB5WZI

> My views are completely based on physics principles. I have endless
> argument with your views on physics.

Then why are ad hominem attacks all you have to offer? Why not share some of you physics knowledge with us? I've got Balanis, Kraus, Johnson, and Hecht on my side. Who's on your side?

> I have never met nor corresponded with Tom D., Tom R. or Roy L. I just
> happen to agree with their public writings.

I suspect Roy L., being a reasonable fellow, is in the process of changing his mind given the latest EZNEC helical evidence. How about you?

Please pick one item of physics with which you disagree with me and let's discuss it in a gentlemanly fashion. There's some pretty savvy people on this newsgroup who agree with me. Perhaps, the argument is only a semantics problem, like the definition of "drop" and "flow". It's really hard to see how an E-field can drop but not flow and an H-field can flow but not drop.

Pick one simple topic upon which you think you and I disagree. So far, you have posted nothing except ad hominem attacks. That's not a good way to impress people and win technical arguments. I think you are a better person than that.

Here's a topic if you can't think of one. How can a one foot long section of transmission line exhibit a phase shift if a one foot long coil doesn't?

# 1378. Re: Current in loading coil, EZNEC - helix

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-27 04:27:46 UTC
From: richardharrison@webtv.net
Message-ID: <12294-417F23C2-524@storefull-3252.bay.webtv.net>
Source record: 87473

Gene, W4SZ wrote:
"However, current is not the same as H-field,--."

No, but current causes the H-field.

An antenna loading coil has volts and amps from both directions in a standing-wave antenna. These two waves create the standing-wave pattern seen along the antenna`s length (including the coil).

The coil has a finite length so the sum of the forward and reflected waves make volts, amps, and impedances which vary from coil end to coil end,

Best regards, Richard Harrison, KB5WZI

# 1379. Re: Gas lines and ground rods

Art Unwin wrote:
"The gas line is "likely grounded" should not be used as a measure of confidence to ground to a gas line."

That`s correct. Plastic pipe is now sometimes used for gas and it certainly won`t serve as a ground.

The questioner wrote:
"Now I know I can`t attach ground to gas line."
His question was about proximity of a ground rod to a gas line. My answer was not to worry about ground rod proximity to a gas line so long as he doesn`t short out the cathodic protection potential which is imposed on a metal line on the feed side of the meter.

Best regards, Richard Harrison, KB5WZI

"Critical" coupling is a coupling that achieves that which is desired in the application involved.
Thus "critical" coupling varies dependent on the situation or application involved which in your
'specific ' application may well be defined as you stated but is not all inclusive..
That's how I see it and what I spoke of is confirmed by NEC and by personal experimentation
If you choose to disagree that is your choice but goes directly to my statement regarding quoting
of text without full understanding.
I have no interest in argueing the fact, try somebody else.

Frank

## 1389. New Butternut question (tunung stub)

Newsgroup: rec.radio.amateur.antenna
Date: 2004-10-27 12:57:21 UTC
From: Mike Coslo <mjc5remove@psu.edu>
Message-ID: <417F9B31.1010908@psu.edu>
Source record: 87484

On my HF6V, it calls for a "tuning stub" of a 1/4 wavelength to tune the antenna at 20 meters. The stub is made of 75 ohm coax, and is 11'4" long, after which the rest of the coax to the shack is 50 ohm.

How exactly does this work? There is an explanation of sorts in the manual, but nothing I can sink my teeth into.

One of the first things I trip over is that an 11'4" piece of 75 ohm coax is not a quarter wave in the 20 meter band - more like 17+ MHz.

The book notes that the 20 meter portion is more like 100 ohms, and the stub allows your rig to see 50.

If the antenna works, that's cool, but I'd sure like to know a little more detail.

Cecil,

I was going to drop this discussion, but I will respond to your request
to share physics knowledge.

1) I will repeat. E-fields, H-fields, voltages, and currents are all
related through some very profound equations. However, <shout> THEY ARE
NOT INTERCHANGEABLE. </shout>

This is not just a matter of semantics. These entities have different
physical meanings, different units, and different dimensionalities.

2) I offered a physics-based explanation for your proposed "current
drop" in the 440 MHz RG-58 example a few days ago. Did you not read that
message before responding to it?

3) A one foot long section of wire and a one foot long section of coil
exhibit similar phase shifts, according to both the theory and the
reported data. What is not correct is the assertion that the coil
exhibits a phase shift consistent with, for example, 20 feet of wire
used to make the coil. The notion that a coil replaces some sizable
portion of the total phase shift in an antenna has been shown to be
incorrect. Experiments reported by Roy and Tom R. convincingly
demonstrate the phase shift behavior of coils.

Doesn't sound dumb - you just missed the original argument. It occurred over on eHam.net, was titled "In Search of 'The Perfect Mobile Antenna'" and overflowed to this newsgroup. W8JI said there is essentially no current change from end to end in a mobile loading coil and used the lumped ideal dimensionless inductor from EZNEC to "prove" his statement. K3BU took issue and the argument still rages.

The article on eHam.net is at:

http://www.eham.net/articles/5998

W8JI's take on the subject is on his web page at:

http://www.w8ji.com/mobile_and_loaded_antenna.htm

K3BU's take on the subject is on his web page at:

http://www.k3bu.us/loadingcoils.htm

My take on the subject is on my web page at:

http://www.qsl.net/w5dxp/current.htm

> Why are
> people arguing about current in a loading coil? NEC, and experiment, seem
> to provide the answer.

Lumped point inductances used by some models are dimensionless and therefore have no current drop. Of course, lumped point inductances don't exist in reality. The Helix feature of EZNEC+ illustrates the change in current through the coil. Based on the quote from Balanis below, the total current through the coil is If+Ib where 'If' is the forward current and 'Ib' is the backward (reflected) current. That is, of course, phasor addition. The net total current, If+Ib, for a 1/2WL dipole is close to a cosine function with the center feedpoint at zero degrees. So Itot = If+Ib = ~Ifeed*cos(degrees), where (degrees) is the number of degrees away from the feedpoint of the dipole. Halfway out one leg of a dipole the current is approximately Ifeed*cos(45) = 0.707*Ifeed (Ifeed is feedpoint current)

The current at the tip of a dipole is Ifeed*cos(zero) = 0 Itot = If+Ib = 0 at the tip of the dipole because the two currents, If and Ib, are equal in magnitude and opposite in phase. (Note: the convention is that the current reflected at

an open-circuit changes phase by 180 degrees. Even though
the current is a phasor, only the Real part exists in reality.
Current in a wire has a magnitude and direction. There are
only two possible directions.)

The total current on the dipole is a standing wave with the
total current decreasing to zero at the tip of the dipole.
If and Ib are flowing in opposite directions and therefore
their phases are rotating in opposite directions. It is that
phase rotation difference that causes If+Ib to be different
at each end of a typical loaded mobile antenna. It's a pretty
simple concept and is explained on my web page above.

Incidentally, the feedpoint impedance of a 50 ohm dipole depends
upon the magnitude of the reflected voltage and reflected current
on the antenna. If a 1/2WL dipole were turned into a traveling-
wave antenna by terminating both ends, the feedpoint impedance
would be hundreds of ohms.
--
73, Cecil http://www.qsl.net/w5dxp
"The current and voltage distributions on open-ended wire antennas are
similar to the standing wave patterns on open-ended transmission lines ...
Standing wave antennas, such as the dipole, can be analyzed as traveling
wave antennas with waves propagating in opposite directions (forward and
backward) and represented by traveling wave currents If and Ib ..."

Hi Frank,
you're right, there shouldn't be any argument. There is more
than one way to make a loading coil. If you will visit Tom Rauch's web
page, you will see that he believes he has a method for making a
superior loading coil for small, mobile antennas. Some of the characters
on this newsgroup have misrepresented what he wrote to assert that he
believes that all loading coils behave as an ideal inductance where
the current at both ends of the inductor are the same. Read what Tom
actually wrote and then go back and look at what these people said he
wrote and you'll see the two aren't the same.

Thanks for the link Yuri. Read the web page, and now understand what is going on. I have an Excel spreadsheet, complete with graph, prepared from a NEC2 model of an inductively loaded monopole. The graph clearly shows the current distribution across the coil. If you are interested I can e-mail it to you, or can post it on the NG. It is only about 50kB, but not sure if it is acceptable to post attachments on a NG.

Thanks Tom, will read the links so will better understand what the arguments are about.

>
> are you accounting for velocity factor?

They do have different lengths for different dielectrics. solid
dielectric is the 11 foot +, and foam dielectric uses a 13 foot + length.

It's likely that velocity factor is involved in that part.

<<beginner alert!>>

Lessee if I have this correct here. Pardon if I seem a little slow, as
I'm new at this.

Since I calculated 16' 6" inch for the middle of the 20 meter band.

And they are using 11' 4" of solid dielectric coax for a stub.

11'4" is around 70 percent of the length of 16'6".

So the solid dielectric velocity factor is around .70 correct?

This would make the foam dielectric around .80 if I'm not all wet.

looking at velocity factors for various cable types, I'm seeing from .66
to .85.

Of course I don't know where they calculated the exact frequency for, and this antenna probably has some other interactions, but it seems to be in the ballpark.

Is this solid, or nonsense?

- Mike KB3EIA -

Now I wonder how that all ties in with changing that 100 Ohm impedance to 50 Ohms?

<<beginner alert off!>>

Thanks, Gene, Please be patient with me.

> NOT INTERCHANGEABLE. </shout>

Is the H-field around a wire proportional to the RF current in the wire?
Is the E-field around a wire proportional to the RF voltage between the
wires? Is the ratio of E-field to H-field fixed by Z0? Do I^2*R losses
affect the E-field and H-field by equal amounts?

> This is not just a matter of semantics. These entities have different
> physical meanings, different units, and different dimensionalities.

Of course that's true. However, they are not unrelated.

> 2) I offered a physics-based explanation for your proposed "current
> drop" in the 440 MHz RG-58 example a few days ago. Did you not read that
> message before responding to it?

Yes, and I have been thinking about an example that would better illustrate
what I was asking. A 1000 wavelength dipole located in outer space would
have less current at the ends than at the source. Since there is no other
path for current, what is the explanation for the decrease in the current
at the ends?

> 3) What is not correct is the assertion that the coil
> exhibits a phase shift consistent with, for example, 20 feet of wire
> used to make the coil.

Because nobody has made that assertion since the original eHam article, it
appears to be a straw man. The coil occupies whatever number of degrees
that it occupies and it does NOT occupy zero degrees.

For instance, using a particular EZNEC segment model of a coil, the
current at the bottom is 1.0 amp and the current at the top is 0.5
amp. Assuming the cosine distribution of standing-wave current is
accurate, the coil occupies about 60 degrees. The whip would occupy
about 30 degrees, the rest of the 1/4WL.

Nobody has attempted to explain how one can obtain 90 degrees of a
1/4WL antenna on 4 MHz using a ten foot (15 degree) whip. That is
one hell of a velocity factor. If the bottom-loading coil really
occupies zero degrees, then the ten foot whip would be forced to

occupy 90 degrees. That is so impossible as to be laughable.

> The notion that a coil replaces some sizable
> portion of the total phase shift in an antenna has been shown to be
> incorrect. Experiments reported by Roy and Tom R. convincingly
> demonstrate the phase shift behavior of coils.

The total current undergoes virtually no phase shift since it is a standing wave. That's in the textbooks and nobody is arguing that point so it's just another straw man.

It's the forward current and reflected current that is undergoing a phase shift through the coil just like they do on a wire standing-wave antenna. Nobody has measured those two current components so the jury is still out on that subject. There is no argument about the phase of the total current that Roy and Tom measured. Please, there are enough arguments already without having to introduce straw men.

If you will look at my phasor diagrams of forward and reflected currents at:

http://www.qsl.net/w5dxp/current.htm

you will see that the phase of the total current is exactly the same in both cases. That's the phase that Roy measured. Since it is a standing wave current, the phase of the standing-wave current is almost constant. It is the magnitude of the standing-wave current that changes and it changes as a cosine function of electrical length in degrees. The coil has an electrical length in degrees. That's what causes the current to be different at the bottom and at the top in a 1/4WL antenna. Assuming the phase shift from the feedpoint current to the tip of the antenna is 90 degrees, if an accurate measurement of the current at the top and bottom of a bottom-loaded antenna coil is made, the number of degrees occupied by the coil can be calculated from

arccos(Itop/Ibottom)

just as it can be calculated between two points on a wire. This assumes that Ibottom is an Imax point on the standing wave.

MK & TELAMON,

My reason for stating that the performance was 'poor' had to do with
